be completed until after twenty-seven days thyroid py but even then it gave less than the normal response.

## Endocrine Assays in Hypothyroidism

these 4 patients with hypothyroidism the adreno cal function was normal in the 1st, a low normal in the deficient in the 3rd (who had been without thyroid py for six weeks only), and grossly deficient in the In each patient the output of 17 ketogenic steroids increased by thyroid therapy and the two deficient nts reached normal levels

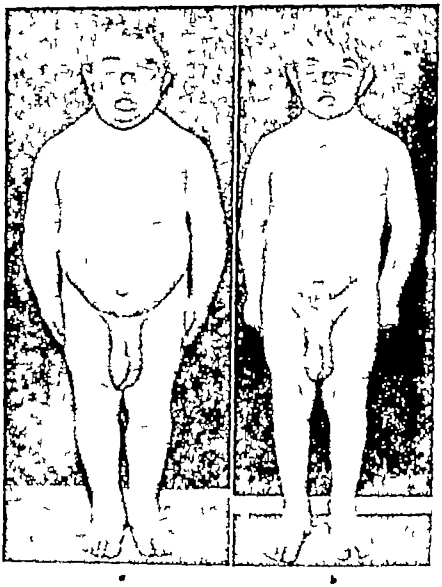
he response of the adrenal cortex to *corticotrophin* tested in 3 patients In the 1st patient the normal ex was fully responsive in the 2nd patient after n days treatment with corticotrophin 60 units y the depressed cortex was moderately responsive ketogenic steroids from 5 mg to 15 mg per 24 hr ), e 3rd patient, after thirty five days thyroid therapy seventeen days treatment with corticotrophin nits daily the partially recovered cortex was capable a moderate response (17 ketogenic steroids from to 13 mg per 24 hr ) Adrenocortical function is efore sometimes but not invariably depressed in cœdema. Statland and Lerman (1950) and Hill l. (1950) came to a similar conclusion In my cases adrenocortical depression was corrected by thyroid apy Beierwaltes and Bishop (1954) have found t the excretion of 17 ketosteroids by myxœdematous nen is subnormal and will usually increase to normal ls even over periods as short as one and a half nths if thyroxine dosage is increased sufficiently

his adrenocortical depression is sometimes regarded the direct effect of hypothyroidism on the adrenal tex— myxœdema of adrenocortical tissue, though tland and Lerman (1950) observe that this depression y be the result of disturbed pituitary function In f the 3 patients described above who were stimulated h corticotrophin the depressed adrenal cortex was able of response while the patients were still hypo roid The response was however far from normal l the central problem remains unsettled for this tial response may indicate that the adrenal cortex sluggish either because it suffers from thyroxine lack because it has been deprived for so long of its nor l stimulus to activity—corticotrophin Indeed both chanisms may be concerned It is certainly possible t the output of corticotrophin is sometimes depressed hypothyroidism

## Water-load Response

In case 3 the water load response was grossly defective d although she might not have fully recovered from her cardiac failure at that time the water load response was still not normal after twenty-one days thyroxine therapy when cardiac failure had long disappeared Throughout this time adrenocortical function was normal or better than normal (stimulated by corticotrophin) In case 4 despite severe and prolonged myxœdema and mild adrenocortical depression, the water load response was fully normal In case 5 in whom myxœdema had followed thyroidectomy and who had been without thyroid therapy for no more than six weeks the water load response was subnormal Both the response and adrenocortical function were improved by a week's thyroid treatment In the cretin (case 6) the water load response was still defective after twenty seven days thyroid therapy but was fully restored after thirty four days treatment

The water load response in myxœdema has been reported to be normal Levy et al (1946) investigating the response to the Kepler test in conditions other than Addison's disease reported a normal response in 3 patients with myxœdema It should be emphasised that the criteria for the Kepler test are not identical with those for the water load response as defined above Gaunt et al (1944) report a normal diuretic response in rats made hypothyroid with thiouracil. Garrod and Burston (1952) refer to unpublished observations in which patients with myxœdema gave a normal diuretic response † However the subject has recently been reopened by Crispell et al (1954) who report a delayed diuretic response in 8 patients with myxœdema This delay was corrected with thyroid sometimes after long continued treatment but in 4 of 5 patients was not corrected with cortisone Those workers conclude that the delay in



Cretin aged 25 showing excessive genital development: a on Feb. 16, 1954, before treatment; b on April 2, 1954, after treatment.

6853-

---

† Since this paper was submitted Garrod and Gilliland have reported that 16 of 18 cases of myxœdema in response to the standard water load exceeded 3 ml per minute and 60 excretion while the other 2 patients showed a poor diuresis (*Proc R Soc Med* 1954 47 880)

diuresis in myxœdema is not caused by hypo adrenalism, and observe that their results allow no conclusion about whether this delayed diuresis is associated with the depression of glomerular filtration-rate which is known to occur in myxœdema (Corcoran and Page 1947, Davies et al 1952) or with increased tubular reabsorption My results confirm that there may be delayed diuresis in myxœdema which is corrected by thyroid therapy but is not restored by improved adrenocortical function

This finding of a defective water load response in hypothyroidism, which conflicts with the previous reports of other workers (although retention of water is a classical feature of myxœdema), could be attributed to the presence of unrecognised cardiac failure It is appreciated that the differential diagnosis between myxœdema with retention of water and myxœdema with congestive cardiac failure may not be easy, indeed much has been written to illustrate this difficulty It is not thought that any of the patients reported here were in cardiac failure when the defective water load response was demonstrated

## The Pituitary in Hypothyroidism

The possibility that hypothyroidism may lead to a decrease in output of corticotrophin from the anterior lobe of the pituitary gland suggests an inquiry into pituitary function in hypothyroidism It is well established that, in the absence of thyroxine, the output of thyroid stimulating hormone is greatly increased This is matched by cellular hyperplasia in the anterior lobe of the pituitary gland Although enlargement of the pituitary gland has often been reported in myxœdema, adequate studies, using modern techniques, of the results of thyroidectomy and of thyroid aplasia on the pituitary gland are rare, therefore the observations of Crane et al (1954) on "thyroid ablated" monkeys are valuable They found that in these monkeys the anterior lobe of the pituitary gland was increased to twice its normal size, with hyperplasia of the beta cells That this excessive growth of tiss [illegible] myxœdema can occur in other situations w is also s [illegible] by my cretin (case 6) (see figure) in the presence of the [illegible]al skeletal retardation (height 3 ft 10 in and bone age 11–12 years) the penis, testes, and scrotum had grown beyond the average adult size The prostate gland was not certainly palpable, and there had been no seminal emissions Moreover, the institution of thyroid therapy stimulated not only androgenic output, shown by the growth of pubic hair (previously absent) and by the increased output of 17 ketosteroids (from 3 to 12 mg per 24 hr ), but also the output of pituitary gonadotropins from 0 to 6, 16, and 18 mouse units per 24 hr Although the output of follicle stimulating hormone was minimal at the time of admission to hospital, there was also ample clinical evidence of the production of anterior pituitary sex hormones The adrenal androgens were unawakened, and possibly the stimulation of luteinising hormone had been lacking It is evident that in this man hypothyroidism, with the increased production of thyroid stimulating hormone, had caused some dissociation in the formation of the pituitary sex hormones It is also evident that thyroxine is not essential for the growth of cells when there is an adequate supply of the tropic hormone

Paschkis et al (1954) report that myxœdematous women of childbearing age often have menorrhagia and metrorrhagia and sometimes polycystic ovaries and endometrial hyperplasia They suggest that these changes may result from the increased output of gonadotropins (follicle stimulating hormone) Hypothyroidism, therefore, can disturb the production of anterior pituitary [illegible] and although its effects are still [illegible] excess or deficiency of individual [illegible] ult

## Endocrine Relations and Hypopituitarism

Since the endocrine relations of myxœdema are as complicated as I have suggested, it is not surprising that the endocrine relations in hypopituitarism are difficult to elucidate I have observed (Hubble 1952) that in anterior-pituitary deficiency, whatever the cause, sexual failure always precedes thyroid and adrenocortical failure which may be long delayed This has been accepted by other workers, and Peters et al (1954) suggest that thyroid failure follows sexual failure, and that adrenocortical failure is always the last to appear Though this observation may sometimes be correct, amenorrhœa in females, with loss of sexual hair, and loss of libido in both sexes indicate more or less definitely the onset of sexual failure, but the assessment of thyroid and of adrenocortical function has only recently become accurate

Many workers have commented on the fact that in hypopituitarism the blood cholesterol level provides an inadequate index of hypothyroidism, and that the basal metabolic rate (B M R ) may be reduced by other factors than a lack of thyroxine (Querido et al 1954, Peters et al 1954) Radio iodine studies and the estimation of protein bound iodine are providing much mor
accurate information about the function of the thyroid

Similarly it is important that in estimating adren
cortical function in hypopituitarism the tests used shou
be precise, sensitive, and specific Peters et al (195
reporting on the sequence of endocrine failure in
patients with hypopituitarism, are content with blo
sugar and serum electrolyte estimations as their in
of adrenocortical function The height of the bl
sugar level is not the result of a specific adrenocor
mechanism, and the estimation of serum electrolyte
reveal only a severe degree of adrenocortical defic
It is therefore not surprising that these workers c
report any case in which adrenocortical deficiency appeared before hypothyroidism declared itself

**Case 7** —A male patient, aged 61, with hypopituitarism associated with a large tumour (probably a craniopharyngioma) The B M R was –5%, the blood cholesterol level was 165 mg per 100 ml , the peak uptake of $I^{131}$ was 29% of the administered dose, and there was no clinical evidence of hypothyroidism Yet the water load response was not only grossly defective (2 8 ml per min in the second hour and 35% total excretion in three hours) but also was easily corrected with cortisone The output of 17 ketosteroids was 2 mg per 24 hr and of 17 ketogenic steroids 4 mg per 24 hr

Here, then, is one patient in whom the thyroid function is complete, by all available tests, while adrenocortical function is deficient Two patients of mine with post partum necrosis of the pituitary have also shown normal thyroid function with defective adrenocortical function

That the endocrine relations of hypopituitarism may still be obscure despite the use of these modern methods is illustrated by the following 2 cases

**Case 8** —A married woman, aged 45 Her menses started at the age of 17 Her only child was born in May, 1928, when she was aged 20 She had a normal confinement, and the baby was breast fed She has had no menses since Axillary and pubic hair had never been profuse but disappeared entirely in the next year or two Subsequently she became tired and sensitive to cold Myxœdema was diagnosed when she was aged 34, and she has taken thyroid gr 3 daily since Libido diminished at the age of 35 and quickly disappeared She presented the total picture of hypopituitarism on admission to the ward on April 27, 1954 Thyroid therapy was stopped two weeks before admission

*Investigations* —The output of urinary gonadotropin and
œstrogen, assayed on four occasions was nil , that of urinar
17 ketosteroids was 1 5 mg per 24 hr , and of urinary
17 ketogenic steroids 3 5 mg per 24 hr The $I^{131}$ peak uptake
was 5% of 23 6 µC The water load response was >1 ml pe
min in the second hour, and 17% in three hours Bi
chemical investigations were normal except for hype
cholesterolæmia The water load response was not corrected
by corticotrophin 60 I U × 7 or by cortisone 50 mg × 13

After treatment with thyroid gr. 3 × 37 and with cortisone 50 mg. × 40 the flow in the first hour was 4·6 ml. per min. and in the second hour 1·2 ml. per min., and the total in three hours was only 33%. Diuresis occurred seven hours after the water load. The patient is in perfect health with cortisone and thyroid therapy.

Case 9.—A married woman aged 50 had undergone fourteen years previously subtotal thyroidectomy for thyrotoxicosis. Her menses ceased at the same time. After an operation for thrombosed piles, five years ago, she had a severe uterine hæmorrhage, and since then she has suffered from fatigue, loss of libido, and sensitivity to cold. Pubic and axillary hair has disappeared during the last five years.

*Investigations.*—Urinary œstrogens were absent from three of four assays. Urinary gonadotropins were 6, 16, 40, and 70 mouse units per 24 hr. (these last two assays were made after thyroid therapy). Urinary 17-ketosteroids were 1·5, 3, 2·5, and 4 mg. per 24 hr., and urinary 17-ketogenic steroids 5, 4, and 7 mg. per 24 hr. The $I^{131}$ peak uptake was 7·2% of 20·1 μC. Biochemical investigations were normal except for hypercholesterolæmia. The water-load response was 3 ml. per min. in the second hour and 32% in three hours. The adrenal cortex was responsive to stimulation by corticotrophin. Neither thyroid nor cortisone fully corrected the water-load response: at the end of a month's therapy the flow was 3·2 ml. per min. in the second hour and the total excretion 50% in three hours.

*Comments*

Case 8 probably had pituitary inadequacy which developed gradually into total pituitary failure after her first and only confinement. Case 9 had postoperative myxœdema and an early menopause with partial adrenocortical failure, including androgen deficiency, after the uterine hæmorrhage five years previously. Both showed a gross defect of the water-load response, which was not corrected by cortisone but is being slowly restored by thyroid therapy.

The delayed diuresis in myxœdema may not be corrected until some months after adequate thyroid therapy has been instituted. This has been so in 2 of my patients and in some of the cases reported by Crispell et al. (1954). Corcoran and Page (1947) found that in 2 patients with myxœdema the renal blood-flow had not returned to normal after two and three months' treatment.

The conclusion to be drawn from these cases is that if adequate cortisone therapy in hypopituitarism has not corrected the delayed diuresis, this defect is associated with predominant hypothyroidism, whether primary or secondary. Thyroid therapy may then take some months to correct the defect. Cortisone restores the water-load response in hypopituitarism within a day or two if it is due to adrenocortical deficiency, whereas thyroid therapy in hypothyroidism restores the renal blood-flow much more slowly.

## Conclusion

One principle emerges from this investigation—i.e., when we are discussing endocrine relations we must not forget the pituitary. The controlling tropic mechanisms are there, control balanced by their target hormones, and no change takes place in the peripheral gland without its accompanying change in pituitary function. This pituitary change may concern not only an excess or a deficiency of the appropriate tropic hormone, but this in turn may cause an altered output of other tropic hormones. Hypothyroidism has been shown to illustrate this possibility.

The sequence of endocrine failure in hypopituitarism allows us another glimpse into the complicated functions of the pituitary. While the maintenance of thyroid and adrenocortical function after sexual failure has occurred may depend partly on the fact that these two glands are allowed some degree of "provincial autonomy," the evidence from endocrine assays suggests strongly that the sex hormones fail first, whatever the nature of the assault in the pituitary. Are they then the end product of cellular function, and is biosynthesis, when the pituitary faces destruction, carried no further than the formation of corticotrophin and thyroid-stimulating hormone? The chemists will one day tell us.

Meanwhile, some will say speculation is useless, and I might agree with them did I not believe that the modern insistence on peripheral mechanisms is obstructing our understanding. We are content to explain the association of thyrotoxicosis and diabetes by a peripheral mechanism—the effect of too much thyroxine on metabolism, on the beta-cells of the pancreas, and on hepatic glycogen—but I have here described 2 cases of diabetes and thyrotoxicosis in which there is evidence of hyperpituitarism—too much corticotrophin, too much growth hormone, and too much thyroid-stimulating hormone.

We may dislike Langdon Brown's notion of the pituitary as "the leader of the endocrine orchestra"—certainly a mechanism which can continue to prod a member of the band who is quite incapable of response while allowing other active members to languish for want of their essential stimulant hardly deserves the title—yet this does not justify us in forgetting that the pituitary must always be the centre of endocrine relations.

## Summary

The best test of adrenocortical function in excess or deficiency is provided by the Norymberski method for assay of the urinary 17-ketogenic steroids; the failure of adrenocortical function is well shown by a defect in the water-load response which is easily corrected with cortisone.

2 patients are described in whom coincidental thyrotoxicosis and diabetes were accompanied by overactivity of the adrenal cortex. It is suggested that these are examples of hyperpituitarism.

The adrenocortical function was depressed in 2 patients with hypothyroidism and was restored by thyroid therapy. There is evidence that this depression of adrenocortical function may be partly mediated through the anterior lobe of the pituitary gland, whose function may be variously deranged in hypothyroidism.

An impaired response to a water load was present in 3 patients with hypothyroidism and was gradually restored by thyroid therapy.

If the defective water-load response in hypopituitarism is not fully corrected with cortisone, a degree of hypothyroidism may be present requiring thyroid therapy which will slowly correct the defective water-load response.

The numerous endocrine assays were made in the Jessop Hospital for Women, Sheffield, and I am very grateful to Dr. G. O. Paine, Mr. L. F. Mitchell, PH.D., and Mr. M. J. Lovel, B.SC., for making this work possible. Miss A. Matthews, B.SC., Sister L. M. Edwards, and Sister J. E. Smedley controlled the laboratory and ward work with exemplary care.

# CORTISONE IN EXOPHTHALMOS

## REPORT ON A THERAPEUTIC TRIAL OF CORTISONE AND CORTICOTROPHIN (A C T H) IN EXOPHTHALMOS AND EXOPHTHALMIC OPHTHALMOPLEGIA BY A PANEL APPOINTED BY THE MEDICAL RESEARCH COUNCIL*

THE conflicting reports of the value of cortisone and corticotrophin (A C T H) in exophthalmic ophthalmoplegia suggested the desirability of a larger inquiry into the usefulness of such treatment of a condition hitherto difficult of control The original interest was in examples of exophthalmic ophthalmoplegia of progressive or “ malignant ” type, but during the course of the trial patients with lesser degrees of proptosis and without ophthalmoplegia were also included The terms proptosis and exophthalmos are used interchangeably in this report

### Scope of the Study

28 patients were treated, 10 men and 18 women, whose ages ranged from 22 to 79 years One case (no 11, table II) features twice in some of the tables, owing to an acute exophthalmic episode developing during the course of observation, and this must be borne in mind in relation to the statistical presentation in the tables.

*Thyroid Status*

Clinical impression of thyroid function, supplemented in many patients by estimations of basal metabolic rate and radio iodine studies, indicated coexisting thyrotoxicosis in 15 patients (53%) at the start of treatment In 12 patients (43%) thyroid status had either been normal throughout the illness or had become so unde

TABLE I—SEVERITY OF EXOPHTHALMOS AND INCIDENCE OF OPHTHALMOPLEGIA AMONG 28 PATIENTS SUBDIVIDED INTO THOSE WITH AND THOSE WITHOUT CHEMOSIS

| Type of exophthalmos | Severity of exophthalmos | | | No. of patients with ophthalmoplegia | No. of patients without ophthalmoplegia |
|---|---|---|---|---|---|
| | Slight | Moderate | Severe | | |
| With chemosis | 0 | 10 | 5 | 12 | 3 |
| Without chemosis | 4 | 10 | 0 | 7 | * |
| Total | 4 | 20 | 5 — 29 | 19 | 10 — 29 |

* One case (no. 11) features twice owing to an acute exophthalmic episode controlled with corticotrophin, developing during the course of observation following an initial period of treatment with cortisone

the influence of antithyroid drugs or surgery. One patient (case 27) was subthyroid

*Exophthalmos, Ophthalmoplegia, and Chemosis*

For purposes of classification severity of exophthalmos has been graded as slight, moderate, or severe, a distinction made on clinical grounds as well as by measurements of proptosis (for the exophthalmometer cannot record exophthalmos as an absolute). Consideration was given to the use of the terms 'fatty' and 'œdematous' but our criteria have only enabled us to state whether the cases have chemosis and œdema or whether these features were absent. The cases are therefore divided into those with chemosis and those without this feature.

The distribution of the types of exophthalmos (i.e. their severity) and the existence of ophthalmoplegia, together with the presence or absence of chemosis among the patients studied, is shown in table I. It will be seen that weakness of the extrinsic ocular muscles complicated the exophthalmos in 18 of the 28 patients. The table shows that patients with chemosis have, on the average, a more severe degree of exophthalmos and more paralysis than patients without chemosis.

## Treatment

In general, cortisone was given in the usual dosage (table II). It is notable that no side-effects from hypercorticism have been seen in this series. Cortisone has been used in 23 patients and corticotrophin in 5 patients (excluding cases 16 and 18, which had small doses of

TABLE II—(*continued*)

| Case no. | Duration | Age | Sex | Type and severity of exophthalmos | Ocular muscle function | Thyroid status | Drug and dosage | Effect of treatment |
|---|---|---|---|---|---|---|---|---|
| 15 | 3½ years | 38 | F | Without chemosis<br>Proptosis moderate | Diplopia on upward movement | Euthyroid | C 200 mg. for 2 days,<br>C 100 mg. for 11 days,<br>C 150 mg. for 4 days | No effect on exophthalmos, ophthalmoplegia, or thyroid function |
| 16 | 5 years | 38 | F | Without chemosis<br>Proptosis moderate | Normal | Euthyroid | C 200 mg. for [illegible] days<br>C 100 mg. for 10 days<br>C 200 mg. for 4 days<br>A.C.T.H. 37.5 mg. for 2 days | No effect on exophthalmos or thyroid function |
| 17 | 10 months | 22 | F | Without chemosis<br>Proptosis moderate | Normal | Thyrotoxic | C 200 mg. for [illegible] days<br>C 100 mg. for 9 days<br>C 200 mg. for [illegible] days | Exophthalmos: Unchanged<br>Thyroid function: More hyperthyroid (B.M.R.) |
| 18 | 1½ years | 68 | M | Without chemosis<br>Proptosis slight | Normal | Euthyroid | C 100 mg. for 13 days<br>C 200 mg. for 5 days<br>A.C.T.H. 25 mg. for 2 days | Exophthalmos: Increased |

| 25 | 1 month | [illegible] | F | Without chemosis.<br>Proptosis slight | Normal | Thyrotoxic | C 100 mg. daily for 21 days | Thyroid function: Thyrotoxicosis controlled (B.M.R.). No other change |
| 26 | 4 months | 41 | F | With chemosis<br>Proptosis moderate | Reduced | Thyrotoxic | C 100 mg. daily for 21 days | Exophthalmos: Slight improvement<br>Ophthalmoplegia: Unchanged<br>Thyroid function: Control of thyrotoxicosis (B.M.R.)<br>Local effect: Great improvement in chemosis |
| 27 | 18 months | 41 | F | With chemosis<br>Proptosis moderate | L.I.O. and L.S.O. paretic | Subthyroid | C 100 mg. daily for 21 days | No effect.<br>Local effect: Improvement slight |
| 28 | 3 months | 48 | F | With chemosis<br>Proptosis moderate | Limited up and out | Euthyroid | C 200 mg. 1st day, then 100 mg. daily for 23 days | Exophthalmos: No effect<br>Ophthalmoplegia: Unchanged<br>Thyroid function: Unaltered<br>Local effect: Definite improvement |

S.R. = superior rectus; E.R. = external rectus; I.O. = inferior oblique; S.O. = superior oblique; C = cortisone; A.C.T.H. = corticotrophin.
Where change in thyroid function was observed as a result of treatment the criteria by which this was measured—basal metabolic rate (B.M.R.) or radio-iodine studies (I )—are indicated.

corticotrophin for two days at the end of a course of cortisone treatment) The duration of treatment exceeded two weeks except in 3 patients (cases 4, 21, and 22), and averaged three weeks in the remainder

4 patients (cases 8–11) were given a diet providing a calculated daily sodium intake of 800 mg All other drugs were discontinued except in 1 patient (case 15), who received thyroid extract grains 2 daily throughout the period of cortisone administration

## Results

The details of treatment and its effect on proptosis and chemosis in individual patients are shown in table II The effect of treatment has been studied in relation to the following points

1 Effect on proptosis and ophthalmoplegia
2 Local effect on chemosis and œdema
3 Effect on thyroid function

### *Effect on Proptosis and Ophthalmoplegia*

The effect of treatment on proptosis has been classed under the following headings

1 Marked improvement—patients showing a reduction in exophthalmos of 5 mm or more in either eye

2 Slight improvement—patients showing a reduction in exophthalmos of 2–5 mm

3 No effect

The over-all results have been disappointing 3 patients (cases 7, 9, and 11b) showed a marked improvement, and 2 of these 3 patients who obtained a substantial degree of measurable benefit from treatment (cases 7 and 11b) received corticotrophin 5 patients (cases 1, 2, 3, 10, and 26) showed a more modest response, classed as slight improvement, which was temporary and not sustained The drug used in these was cortisone In no case has a permanent reduction in proptosis occurred and later relapse has always taken place In 3 patients (cases 5, 14, and 18) the exophthalmos slightly increased during treatment

Improvement in ocular muscle function occurred in parallel with regression of proptosis in 4 patients (cases 2, 7, 9, and 11) with consequent decrease in the area of diplopia It was notable that the muscles of elevation were usually the first and generally the most severely affected, and were also the first to show functional recovery

Improvement in chemosis was the most constant response and improvement has occurred in the 15 patients who showed this feature

Analysis of the results shows that improvement in proptosis was limited to those patients with ophthalmoplegia and was similar in the group with and the group without chemosis exophthalmos unaccompanied by ocular muscle weakness was uninfluenced by treatment (table III)

Table IV shows that there is a tendency for the proportion of patients showing improvement in exophthalmos to decline with increasing duration of the condition, but the numbers are too small for a firm conclusion to drawn The improvement in ophthalmoplegia was correlated with duration of the complaint

TABLE III—EFFECT OF TREATMENT ON EXOPHTHALMOS RELATED TO INCIDENCE OF OPHTHALMOPLEGIA

| Type of exophthalmos | Total no | Patients with ophthalmoplegia | | Patients without ophthalmoplegia | |
|---|---|---|---|---|---|
| | | No showing improvement in exophthalmos | No change or worse in exophthalmos | No showing improvement in exophthalmos | No change or worse in exophthalmos |
| With chemosis | 15 | 5 | 7 | 0 | 3 |
| Without chemosis | 14 | 3 | 4 | 0 | 7 |
| Total | 29* | 8 | 11 | 0 | 10 |

* Case 11 features twice

TABLE IV—EFFECTS UPON CHEMOSIS, EXOPHTHALMOS, OPHTHALMOPLEGIA IN RELATION TO THE DURATION EXOPHTHALMOS

| Duration | Chemosis | | Exophthalmos | | Ophthal plegia | |
|---|---|---|---|---|---|---|
| | No of cases | Improved | No of cases | Improved | No of cases | Im |
| Less than 6 months | 5 | 5 | 6 | 3 | 5 | 1 |
| 6 months–2 years | 6 | 6 | 13 | 3 | 8 | 1 |
| 2 years + | 4 | 4 | 10 | 2 | 6 | 2 |
| Total | 15 | 15 | 29* | 8 | 19* | 4 |

* Case 11 features twice

### *Effect of Treatment on Thyroid Function*

15 patients (53%) were hyperthyroid before tre ment, and after treatment the level of thyroid functi was depressed in 8 of these The improvement in thy toxicosis was attended in half of these patients by so improvement in exophthalmos, in those patients who thyroid hyperfunction remained unaltered by treatme no local benefit occurred The numbers are too few suggest any difference between the cortisone and cortico trophin groups It is possible upon occasion that modifica tion of coexisting thyrotoxicosis might be a factor bearing upon the success of treatment A study of the case records, however, shows no further evidence therapeutic indication, and it seems impossible to select in advance those patients with thyrotoxicosis who are likely to respond

Among 13 euthyroid patients some depression thyroid function was recorded in 3 cases under treatme

### *Effect of Sodium Restriction*

4 patients (cases 8–11) were given a diet providing daily sodium intake of 800 mg during the period administration of cortisone or corticotrophin Only patient (case 8) failed to derive objective benefit Sodi balance determinations did not show any clear evidence of a saline diuresis, though in general a negative sodium balance was established (Chandler and Hartfall 1952)

## Discussion

28 patients with exophthalmic ophthalmoplegia have been treated with cortisone or corticotrophin At the dosage used no beneficial effect was observed in patients, 5 showed slight temporary improvement and 3 responded well This difference in individual respo is reflected in the publications of other investigat (Lederer and Hambresin 1950) The reasons for the disparity are not immediately obvious, though a rec report (Kinsell et al 1953) suggests that the do employed in this trial has been inadequate Kinsell et advised the intravenous administration of corticotrop (20–40 units per litre) throughout the first three d of treatment, together with 200–600 mg of cortisone the oral or intramuscular route, daily 9 patients trea by this scheme of dosage obtained, without except significant decrease in proptosis within forty eight ho of commencement, an improvement maintained by c tinued treatment with corticotrophin gel These auth emphasised that very prolonged administration may required in some patients, and the high incidence untoward effects that attended such treatment is in sh contrast to the experience in this trial The conspicu therapeutic successes reported by Kinsell et al wo seem to require that a considerably higher dosage cortisone and corticotrophin be employed in any fu work (Dayton, Okie, and Beierwaltes 1954)

The best results in this series were obtained in those patients whose exophthalmos was of recent origin or had suddenly and rapidly progressed The most striking and constant clinical finding was the improvement in chemosis in each of the 15 cases where this feature was present

If local withdrawal of fluid from the orbital tissues and relief of orbital œdema were the factors responsible for clinical improvement (Campbell 1952) such an effect could only be expected in exophthalmos of recent origin before fibrotic changes have occurred in the ocular muscles and tissues Support for this hypothesis is afforded by the results of treatment seen in relation to the duration of history (table IV) for of 6 instances of exophthalmos of less than six months duration 3 showed improvement One of these (case 11b) had developed malignant exophthalmos after the incision of an abscess under general anæsthesia the rapid control of this patient's post anæsthetic increase in proptosis by corticotrophin was highly encouraging Of 23 patients in whom exophthalmos had been present for longer than six months only 5 obtained benefit from treatment

The patients in whom exophthalmos and thyrotoxicosis coexist form a group of particular therapeutic difficulty In this trial depression of thyroid function was observed in 8 of 15 patients initially thyrotoxic Of these, 4 derived some benefit from treatment regression of exophthalmos occurring concomitantly with apparent control of the thyrotoxic state 13 patients were euthyroid at the start of treatment and 4 of these obtained improvement in exophthalmos The difference in response between the two groups of thyrotoxic and euthyroid patients is not statistically significant but the depression of coexisting thyroid hyperfunction observed in some of the patients treated with cortisone or corticotrophin might perhaps suggest that these drugs are worthy of trial where thyrotoxicosis accompanies exophthalmos. There were however no specific features except perhaps chemosis which enabled a more confident selection to be made of suitable patients and further information and study are required here

The results in 10 patients who showed exophthalmos unaccompanied by ocular muscle weakness have been entirely disappointing and no benefit from treatment has been observed Most of these patients belonged to the group without chemosis and œdema

It is possible that the dietary restriction of sodium may be responsible for clinical improvement Of the 4 patients submitted to a low sodium intake 3 showed appreciable improvement

### Conclusions

1 No significant benefit occurred in the majority of patients suffering from exophthalmos and/or exophthalmic ophthalmoplegia from treatment with cortisone or corticotrophin (A C T H ) Inadequate therapeutic response may in some instances be referable to inadequate and insufficiently prolonged dosage

2 Cortisone and corticotrophin are worthy of further trial in patients with progressive exophthalmos of sudden or recent onset with chemosis

3 A group of patients whose proptosis was unaccompanied by chemosis and œdema and usually without ophthalmoplegia showed the least response to treatment

4 Coexisting thyrotoxicosis was reduced in a number of patients and half of these patients derived local benefit from treatment

5 If further trials are undertaken it is suggested that the dosage of cortisone and corticotrophin be considerably increased and special consideration be given to the use of serial intravenous corticotrophin infusions perhaps combined with dietary restriction of sodium

The panel wish to record the help given by Dr G N Chandler in the preparation of this report

# BRONCHOSCOPIC APPROACH FOR MEASURING PRESSURE IN LEFT AURICLE, PULMONARY ARTERY, AND AORTA

P R ALLISON
B Sc , Ch.M. Leeds, F R C.S
NUFFIELD PROFESSOR OF SURGERY IN THE UNIVERSITY OF OXFORD

R J LINDEN
M.B Leeds
LECTURER IN PHYSIOLOGY IN THE UNIVERSITY OF LEEDS

SINCE the original papers were published on puncturing the left auricle through a bronchoscope (Facquet et al 1952 1954, Allison and Linden 1953) further experience of the method has been gained, a greater facility in the interpretation of the curves has been acquired and the technique has been extended to the measurement of pressure in the pulmonary artery and the aorta

With thoroughly effective local anæsthesia and smooth bronchoscopy puncture of the heart or of the great vessels is no more uncomfortable than simple bronchoscopy Such punctures were done on 121 patients without causing illness or death and 67 of them are reviewed here

### Method

*The apparatus* was similar to that previously described by Allison and Linden (1953) but was improved by the use of a shorter thicker walled wider bore Polythene tube which is now 25 cm long with 4 mm bore and wall 1 3 mm thick The resulting increased rigidity of the apparatus ensures a higher natural frequency of the recording system and prevents oscillation of the polythene tubing

*Puncture of left auricle*—When the bronchoscope is passed down the right side of the mouth it is usual to puncture the anterior wall of the left main bronchus 0 5–1 0 cm. below the carina Whichever side is used in the approach it is essential to direct the bronchoscope and needle along the line of the sternum When the pulmonary arteries are greatly enlarged the space between them at their origin may be so small that the left auricle is obscured , the arteries are then more liable to be pierced within the pericardium Although no obvious harm has resulted from this, at operation the pericardial fluid has been found stained for the large arteries are obviously more liable to bleed under increased tension When they are very large they may be avoided by passing the bronchoscope down the right main bronchus for 1–2 cm. to reach beyond the level of the arteries, and the auricle may then be reached by puncturing the anteromedial wall of the right bronchus

*Puncture of the pulmonary artery* is better done extrapericardially The bronchoscope is withdrawn into the trachea just above the carina the head of the patient is depressed further and the needle passes through the anterior wall of the trachea

*Puncture of aorta*—The aorta can be reached by inserting the needle 2–3 cm higher up the trachea than is done to reach the pulmonary artery

*Tracings*—In all the tracings an electrocardiogram and a phonocardiogram were recorded to facilitate the recognition of the individual waves of the pressure-pulse contours Pressure records were taken with the centre of the manometer membrane levelled to the manubrium

sternum, and this point is taken as the zero reference point in all the figures

## Results and Discussion

*Pulmonary Artery*

The pulmonary artery tracings, though valuable records, have not so far added anything to the knowledge gained from cardiac catheterisation To be able to take a record of pulmonary artery pressure and a left-auricular pressure at the same examination obviates the need for catheterisation and is particularly valuable for long-term follow up, for it can be repeated indefinitely A typical record of pulmonary artery pressure taken through the bronchoscope immediately after recording left auricular pressure is shown in fig 1

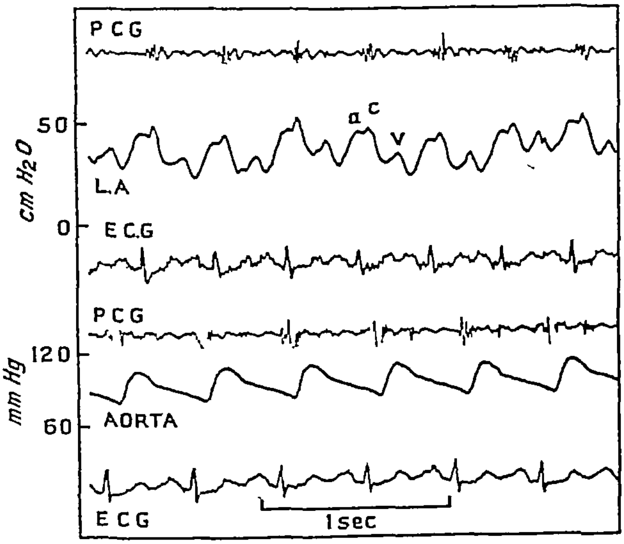

Fig 2—Left auricular (L.A.) and aortic pressures in a patient with mitral stenosis, showing absence of aortic incompetence.

*Aorta*

In some patients the aortic pressure was recorded, but the true value of this has not yet been assessed A bronchoscopic aortic pressure record is shown in fig 2 Clinically, the patient from whom this tracing was taken had mitral stenosis, and in addition the physical signs suggested either aortic or pulmonary incompetence The aortic record showed that there was no aortic incompetence

*Left Auricle*

The left auricular pressures in normal hearts i patients in this abnormal position and with a bronch scope in place were recorded in 5 patients with disea lung and no cardiovascular disease A typical exa of a left auricular pressure taken from a patient with normal heart is seen in fig 3 The *a* wave of systole is seen clearly starting 0 1 sec before the R of the electrocardiogram (E C G ) The *c* wave, in with the onset of ventricular contraction, is very and occurs 0 04 sec after the R wave It is notice mainly because of the abrupt alteration in gradient this point This is followed by the prominent *v* about 0 1 sec after the end of the T wave of the

61 patients with mitral disease, in whom the diagn was made with certainty, were included in this In 48 of them the diagnosis was confirmed at operat when examination of the external surface of the revealed the position of thrills, and a finger inside the auricle decided the presence or absence of a regu stream In the remaining 13 the diagnosis, determ on clinical and radiological evidence, was also be dispute but not confirmed by operation

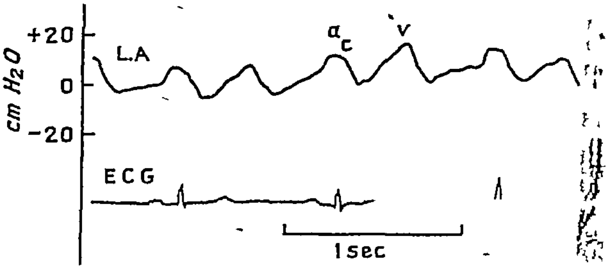

Fig 3—Left auricular pressure typical of normal heart.

The results fall naturally into two groups pa with sinus rhythm, and those with auricular fibrilla It is necessary only to attempt to differentiate betw mitral stenosis and mitral regurgitation within group

Of those with sinus rhythm 28 had pure mitral sten (26 confirmed at operation), and 6 were diagn clinically and radiologically as having mitral regu tion A typical record from a patient with pure stenosis is seen in fig 1 The appearance of the pulse contour is similar to that found in normal tra but the pressures at all points are raised The *a*, *c*, *v* waves are distinguished easily, and the magnitude the *v* wave is less than that of the *a* wave

The records from the 6 patients with sinus rhythm mitral regurgitation, though few, show different pres pulse contours They are similar to those obtained dogs by Wiggers and Feil (1922), who produced regu tation by preventing the mitral valve from closing d

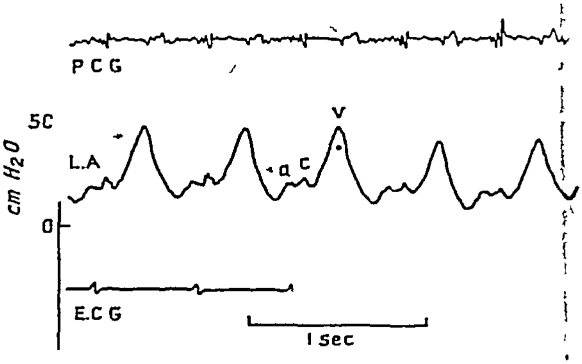

Fig 4—Left auricular pressure in a patient with mitral and sinus rhythm

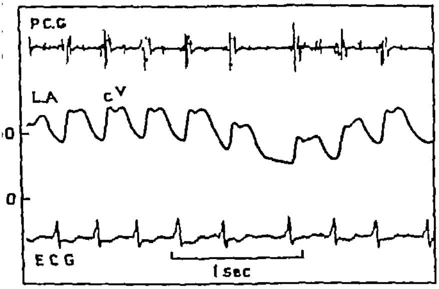
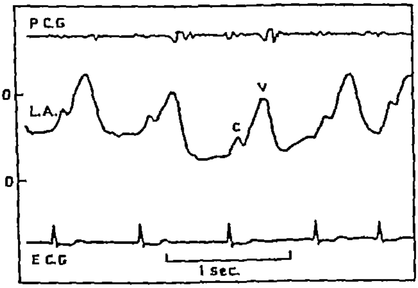


g 5—Left-auricular pressure in a patient with mitral stenosis and auricular fibrillation.

ntricular systole. In these circumstances the left uricular pressure pulse contour showed a rise in pressure arting not in early systole but in mid to late systole ith a relatively high *v* wave. A record from a patient ith pure mitral regurgitation and sinus rhythm is seen fig 4 Again the three waves of the central venous ulse are seen clearly and there is a characteristic igh-climbing *v* wave

In patients with auricular fibrillation the auricular ontraction wave is absent, and each cardiac cycle begins ith an initial abrupt rise of pressure synchronous with e beginning of ventricular systole Records from 2 atients of whom one had auricular fibrillation and itral stenosis and the other auricular fibrillation and itral regurgitation are shown in figs 5 and 6 respectively These also show the increase in height of the *v* wave relative to the remainder of the pressure-pulse contour when a regurgitant stream is present



ig 6—Left-auricular pressure in a patient with mitral regurgitation and auricular fibrillation.

We do not claim that all cases may be divided strictly nto two groups those with stenosis and those with regurgitation because many patients have mixed lesions A record from such a patient, in sinus rhythm is seen in fig 7 On clinical and radiological findings this patient appeared to have pure mitral stenosis, but at operation there was a small regurgitant stream to be felt coming through the mitral valve. Although some regurgitation was suggested by the high *v* wave of the pressure pulse contour it was impossible to assess the degree However the occurrence of the mixed lesion of mitral stenosis and regurgitation appeared to be more common in the group with auricular fibrillation In accord with this Little (1951) thought that where the ventricular contraction is not immediately preceded by *an auricular contraction* regurgitation into the auricle always takes place However, it seems possible that this depends to some extent on the length of the previous diastole

In many patients with both stenosis and regurgitation the pressure tracing in the left auricle remains constant in successive cycles each wave form being a replica of the preceding one and a pattern for the one to follow, but occasionally, it seems regurgitation may occur in one cycle and not in another with the result that the wave contours vary Such a record is seen in fig 8 in which cycle 1 is typical of mitral stenosis whereas cycle 2 suggests regurgitation Closer examination shows that the left-auricular pressure-cycle 2 with the high-climbing *v* wave typical of mitral regurgitation is immediately preceded by a relatively long diastole and cycle 1 in keeping with mitral stenosis is preceded by a short diastole It seems that in this particular patient there was an appreciable regurgitation through the mitral valve during ventricular contraction when this followed a long diastole Wiggers and Feil (1922) produced evidence which supports this when they found that The regurgitation is definitely increased in slow beats Thus we infer that a patient with mitral stenosis may have an incompetent valve when the heart is beating slowly, though this may not be so when the heart is beating quickly Here is obviously a matter for further investigation

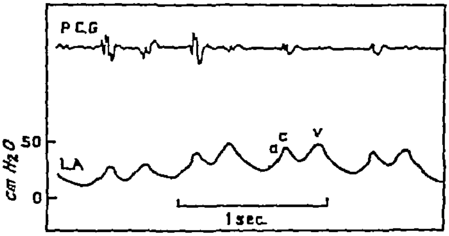


Fig. 7—Left-auricular pressures in a patient, with mitral stenosis and sinus rhythm in whom a small regurgitant stream was found at operation

After examination of the form of the tracings a quantitative study was attempted to see if a finer distinction could be made between stenosis and regurgitation Pressures were measured at two points the *z* point (Werle et al 1942) corresponding to the beginning of ventricular systole—i.e the beginning of the *c* wave—and the top of the *v* wave These were chosen because it was thought that the difference between them if great would indicate the presence of regurgitation for the auricular pressure in mitral incompetence rises during this interval The presence or absence of the

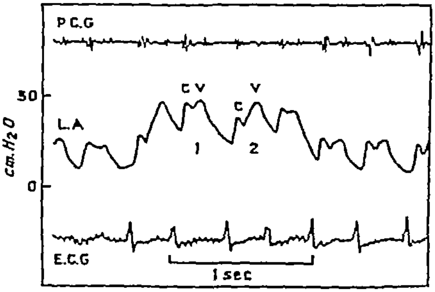

Fig 8—Left-auricular pressure in a patient with mitral stenosis and auricular fibrillation showing cardiac cycle 1 typical of mitral stenosis and cardiac cycle 2 typical of regurgitation.

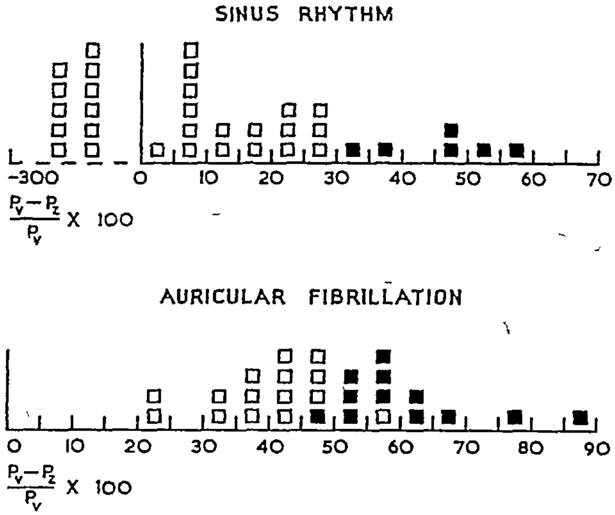

Fig 9—Analysis of left-auricular pressure-curves of 61 patients with mitral disease. Each open square represents a patient with stenosis, and each closed square a patient with regurgitation Along the abscissa are the left auricular mitral values derived from each patient s pressure-curve (explained in the text)

negative wave at this time was ignored, because it is considered to be due to dragging down of the valve ring by ventricular contraction

Many things affect the pressure in the left auricle, and, when all these are subject to variation from one patient to the next, it is difficult to assess the part played by any one of them in a group study With our manometers calibrated against an atmospheric zero levelled to the manubrium sterni it was obvious that respiration would affect the pulse contour, with the result that different points on the same cardiac cycle would be affected by different intrathoracic pressures To circumvent this difficulty all the measurements were taken from a cardiac cycle in an expiratory pause

Other factors affecting the pressure in the auricle are the volume of blood contained in the pulmonary vein-auricle system, the rate of flow of blood to the the volume-elasticity coefficient of the left auricle, an systemic arterial and left ventricular pressures F patient to patient these factors vary independentl the presence of regurgitation and would mask any att to indicate this regurgitation by the direct compa of records from different patients

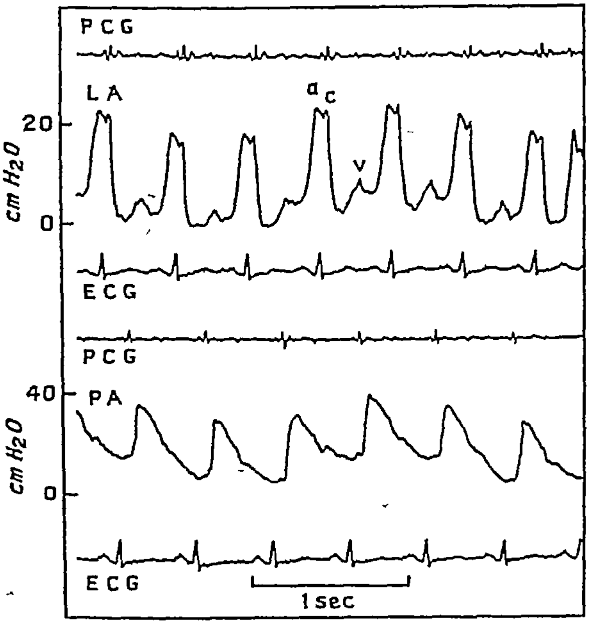

Fig 10—Left-auricular and pulmonary-artery pressures in a patient with mitral stenosis and neurosis, showing said pressures within normal limits

This difficulty has been largely overcome by the difference between the pressures measured at the of the $v$ wave and the $z$ point ($P_v - P_z$) as a of the pressure at the top of the $v$ wave ($P_v$) Thu obtain the expression $\frac{P_v - P_z}{P_v} \times 100$ This provide with a number which we have called the left-auri mitral value This is related to the pressures at and $z$ points but is little affected by the indiv patient variation which occurs in both numerator denominator and, to some extent, is cancelled out

The figure from this expression was worked out the left auricular pressure pulse curves of 61 p with mitral disease where the diagnosis was c determined

Fig 9 shows the results of this analysis In p with sinus rhythm, stenosis is clearly distinguished regurgitation by the left auricular mitral values In group with a left auricular mitral value of 25–30 patient (see fig 7) had a value of 29 and yet had a regurgitant stream at operation, being the only on this group to have any regurgitation at all

Fig 9 also shows the results from patients with disease and auricular fibrillation At first sight it app that the distinction between those with stenosis those with regurgitation, as one would expect, is clear-cut One patient, although having fibrillation a mitral value of 52, had a qualitative left- pressure-tracing like that of pure stenosis and had stenosis at operation Another patient, with fib who clinically and radiologically had mitral regurgi had a mitral value of 49, which indicated sten However, although the left-auricular pressure showed a rapid heart with the majority of cardiac c indicating mitral stenosis, an occasional longer dias was followed by a typical regurgitant curve It w indeed be surprising if there were a clear cut d between the two conditions, for many patients have stenosis and regurgitation

The above analysis is obviously very empirical spite of the attempt to justify it by simple mathem Many more patients must be examined before its v can be assessed Mitral regurgitation, when present, be diagnosed clinically and radiologically in most patie but in some there is uncertainty or a firm diagnosi subsequently found to be inaccurate It remains to seen if the method described above extends the po bilities of diagnosis into this latter group

That this simple technique is useful in assessing postoperative progress of patients after mitral valvoto is certain The patient whose symptoms recur may working too hard, he may have progressive pulmon vascular disease, or the valve may be narrowing ag Puncture of the left auricle is a quick and reliable wa deciding between these and other possible explanat for a raised pressure will surely indicate stenosis

A third use for this technique, not entirely separ from the above mentioned, is to help to differenti patients in whom the mitral lesion is not responsible all the symptoms A normal low left-auricular press is a contra indication to operation on the mitral va as in the following case

A married woman, aged 38, complained of a gripping c pain, breathlessness, dizziness, fainting attacks, and swell of the face, hands, and ankles The breathlessness was s to make it difficult for her to walk far and impossible to l

Specific therapy was withheld until *Sh sonnei* had been isolated from the stools. Treatment was considered to have been successful when the first six specimens taken after the end of treatment were negative for *Sh sonnei* and to have failed when *Sh sonnei* was isolated from any of these specimens. In each group the interval between the end of treatment and the sixth negative specimen averaged 9 days, with a range of 6–16 days in the tetracycline and streptomycin groups and 7–14 days in the phthalyl sulphathiazole group. All the follow-up specimens were taken while the patients were still in hospital.

### Bacteriological Methods

Fæcal specimens and occasionally rectal swabs were plated on to deoxycholate citrate agar directly (Hynes 1942) and after overnight incubation in selenite broth (Hobbs and Allison 1945). *Sh sonnei* was identified by colonial morphology on deoxycholate-citrate agar and by slide agglutination with S–R Sonne antiserum (Standards Laboratory).

Strains isolated from the tetracycline series were tested for sensitivity to tetracycline by a doubling dilution technique in tubes. A stock solution of 2500 µg per ml of tetracycline hydrochloride in distilled water was prepared each week and kept at 4°C. Further dilutions were made in a medium of the following composition:

TABLE II—DOSAGE OF TETRACYCLINE AND PHTHALYL SULPHATHIAZOLE

| Age (yr) | Tetracycline | | Phthalyl sulphathiazole | |
|---|---|---|---|---|
| | Regimen | Total dosage (g) | Regimen | Total dosage (g) |
| Less than 5 | 125 mg 6 hrly for 7 days | 3 5 | 0 5 g 6 hrly for 7 days | 11 |
| 5–15 | 250 mg 6 hrly for 7 days | 7·0 | 1 0 g 6 hrly for 7 days | 28 |
| More than 15 | 500 mg 6 hrly for 7 days | 14·0 | 2·0 g, 6-hrly for 7 days | 56 |

| | |
|---|---|
| Peptone | 2 0 g |
| Sodium chloride | 0 5 g |
| Glucose | 2 0 g |
| Distilled water | 100 ml |
| pH adjusted to | 7 6 |
| Andrade's indicator | 1·0 ml. |

A series of doubling dilutions of tetracycline in 1 ml volumes of this medium were prepared and 0 02 ml of a 1 in 100 dilution of a 24-hour broth culture of *Sh sonnei* was added to each tube. The sensitivity of the organism was taken to be the smallest final concentration of tetracycline that completely inhibited growth, judged by visible turbidity after 22–24 hours' incubation at 37°C. Strains isolated from the series treated with phthalyl sulphathiazole were tested for sensitivity to sulphathiazole by the disc technique described by Davies (1954).

### Results

The results of treatment are summarised in table III. Treatment was successful in 26 of the 27 patients treated with tetracycline, in 11 of the 32 treated with phthalyl sulphathiazole, and in 9 of the 25 treated with oral streptomycin.

TABLE III—RESULTS OF TREATMENT WITH TETRACYCLINE, PHTHALYL SULPHATHIAZOLE AND ORAL STREPTOMYCIN

| Result | Tetracycline | Phthalyl sulphathiazole | Oral streptomycin |
|---|---|---|---|
| Success | 26 (96%) | 11 (34%) | 9 (36%) |
| Failure | 1 (4%) | 21 (66%) | 16 (64%) |
| Total | 27 | 32 | 25 |

The strains isolated before treatment in 24 of the 27 cases treated with tetracycline were tested for sensitivity to tetracycline. All of them showed a uniform sensitivity to 4–8 µg of tetracycline per ml. All the strains isolated during treatment showed a similar sensitivity. The Oxford staphylococcus was sensitive to 0 5 µg of tetracycline per ml. A dosage of 0 5 g of tetracycline 6-hourly produced serum tetracycline levels of 4–5 µg per ml (Putnam et al 1953) and fæces tetracycline levels as high as 2230 µg per g of wet stool (Maynard et al 1953).

In the phthalyl sulphathiazole group 31 of 32 strains isolated before treatment were tested for sensitivity: fourteen were sensitive and seventeen resistant to sulphathiazole. Davies (1954) tested strains of *Sh sonnei* both by the disc technique and by inoculating about 150 viable organisms on to nutrient agar containing 5% lysed horse-blood and various concentrations of sulphathiazole. Strains recorded as sensitive by the disc technique were completely inhibited by sulphathiazole 1 mg per 100 ml by the other method; and strains resistant by the disc technique were not inhibited by sulphathiazole 50 mg per 100 ml.

The results of sensitivity tests with streptomycin are not given, because only a few strains were tested.

### Discussion

The number of patients, the age-distribution, and the interval between the onset of the disease and treatment were similar in each group. Although the tetracycline and the phthalyl sulphathiazole groups were strictly comparable, the streptomycin series differed slightly in that many of the patients were treated before March 1954. Successful results were obtained in only a third of the patients treated with phthalyl sulphathiazole or with oral streptomycin, whereas only 1 failure was recorded in the 27 cases treated with tetracycline. From this patient a scanty growth of *Sh sonnei* was obtained from a specimen taken on the second day after the end of treatment, but the following six specimens were negative without further treatment. However, in 1 case treated with tetracycline where twelve negative specimens were required before transfer to an institution a scanty growth of *Sh sonnei* was isolated from the twelfth specimen, although the preceding eleven were negative. This case has been classed as successfully treated because the first six specimens after the end of treatment were negative. In several of the patients treated with tetracycline the fæces were still positive on the 3rd and 4th days of treatment. We therefore feel that it would be unwise to reduce the duration of treatment to less than the 7 days that we have adopted. It is also possible that better results would have been obtained with oral streptomycin if the treatment had lasted longer. Most of our patients were given streptomycin for 3 days because this was the length of treatment used by Forbes (1953).

All the patients were nursed with full barrier technique, but reinfection may explain some of the failures (Vollum and Wylie 1946), though patients in all three groups were open to similar risks.

We found no toxic reactions to any of the drugs used. This confirms the low toxicity of tetracycline reported by Finland et al (1954), but the number of cases that we have treated is small and no special study of possible toxic effects was made.

Testing for sulphonamide sensitivity before treatment proved of little value in predicting the result of treatment with phthalyl sulphathiazole.

In 14 patients from whom sensitive strains were isolated before treatment there were 5 successes and 9 failures, compared with 5 successes and 12 failures in 17 patients from whom resistant strains were originally isolated. In 2 cases resistant strains were recovered after treatment although a sensitive strain had originally been isolated It is uncertain whether this was due to the development of resistance during sulphonamide therapy or to cross-infection The results of these sensitivity tests show that the failure of sulphonamide treatment in many of these cases cannot be attributed to sulphonamide resistant strains

### Conclusions and Summary

In a small trial we have compared the values of tetracycline, phthalyl sulphathiazole, and oral streptomycin in the treatment of Sonne dysentery Of 84 bacteriologically proved cases 27 were treated with tetracycline, 32 with phthalyl sulphathiazole, and 25 with oral streptomycin

Treatment was successful in only a third of the patients who were given phthalyl sulphathiazole or oral streptomycin, whereas there was only 1 failure with tetracycline Under the conditions of this investigation tetracycline proved superior to phthalyl sulphathiazole and oral streptomycin in effecting bacteriological cure

All the strains of *Sh sonnei* tested were sensitive to 4–8 µg of tetracycline per ml Sulphonamide sensitivity tests were of little value in predicting the results of treatment with phthalyl sulphathiazole

We thank Dr D C Liddle, physician superintendent, Monsall Hospital, and Dr M T Parker, director, Public Health Laboratory, Manchester, for their help and advice, and Dr A T. Mennie, medical director, Lederle Laboratories, for supplying the tetracycline ('Achromycin') used in this investigation

# RELIEF OF PAIN IN INCURABLE CANCER

R M Maher
M D Lond, B Sc Lpool, M.R C P
CONSULTING PHYSICIAN, ROCHDALE HOSPITAL GROUP AND OLDHAM COUNTY BOROUGH

THE purpose of this article is to describe new and wider applications of intrathecal therapy for relieving the pain of incurable cancer

Intrathecal therapy aims at selective cell destruction at the posterior root ganglia Introduced by Dogliotti (1931) for sciatic pain, and developed by Saltzstein (1934) and Stern (1934), it was applied with great success by Greenhill and Schmitz (1935, 1936) and Greenhill (1947) to pelvic carcinoma They used 0 75 ml of absolute alcohol, which floated *upwards* to the ganglia Complete relief of pain ensued in 60% of group III and IV cases, and partial relief in 10%

Last year it occurred to me that it would be an advantage to use a heavy "carrying solution," which could convey more than one destructive agent, thus increasing the therapeutic possibilities Moreover, a dense solution would be simpler to control—it is easier to lay a carpet than to paper a ceiling Phenol and silver nitrate were the agents I employed, with glycerin or propylene glycol as the vehicle

Injected intrathecally phenol can cause cord destruction (This was the subject of a recent case in law) If th [illegible] l is held in glycerin, however, its diffusion is at a minimum, and when injected intrathecally it falls downwards (sp gr of glycerin, 1 25, sp gr of cerebrospinal fluid, 1 007) With the patient on his side (as for lumbar puncture) it falls to the posterior root ganglia of his lower half (fig 1) Injected at the appropriate level it will usually cause permanent anæsthesia over the painful area Fig 2 shows the chief components influenced Motor units are not affected, their cell sta being well out of the way in the anterior horn Fu components affected lie in the posterior root

Fig 1—Radiograph after injection of ' (15 parts) and phenol (1 part) Resu anæsthesia over 1st, 2nd, and 3rd on inner side of arm, gave complete of pain

The aim is to select the group of smaller non-med C units of Erlanger et al (1926) The large A type proprioceptive units must be left intact This depend the concentration of the mixture, the optimum strength phenol in glycerin being 1 in 18 to 1 in 20 Such concentration appears to give the correct select affecting pain and touch fibres only, with loss of cutan sensation over the pain area—the only clear indicatio relief Cell selection in these circumstances is apparen on a size basis

### Agents and Procedure

0 2–0 3 ml of heavy cinchocaine hydrochloride ('Nu caine') (*the type used in spinal anæsthesia*) was employed a test agent

1 0–1 7 ml of 1 part of phenol in 18–20 parts of glyce well mixed with 0 1 ml of sterile water per ml, was agent used to provide permanent anæsthesia (If m water is added the phenol is activated and requires dilu to half)

1 ml of gr $^1/_{100}$ silver nitrate in glycerin was occasion employed when phenol proved inadequate

Largely for psychological reasons, the operation sho be carried out at the bedside For injection, the pat

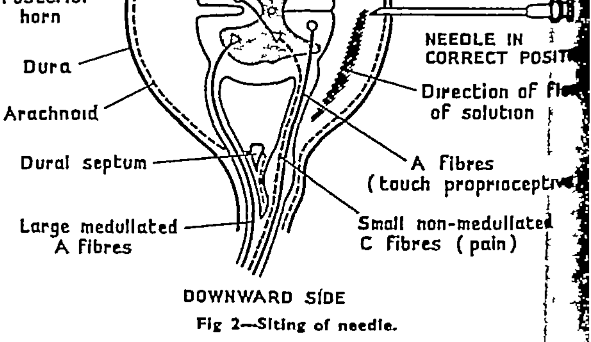

Fig 2—Siting of needle.

lies on his painful side in the lateral lumbar puncture position at the edge of the bed (fig 3A) Puncture is often best performed in the sitting position, and for injection the patient is carefully lowered on to his side. Sacral intrathecal injection is an exception the patient remaining seated for both puncture and injection

The needle is moved forward carefully millimetre by millimetre, and once cerebrospinal fluid appears the needle is advanced 1mm farther This prevents injection of the agent into the subdural space which might result from recession of the arachnoid following removal of C.S.F If the patient experiences bilateral ' root pain the needle has been inserted too far causing dragging of the nerve roots from touching the cord When C.S F flows, and before any injection is made the patient is rotated backwards so that the needle and syringe point upwards at an angle of 45° with the horizontal (fig 3B)

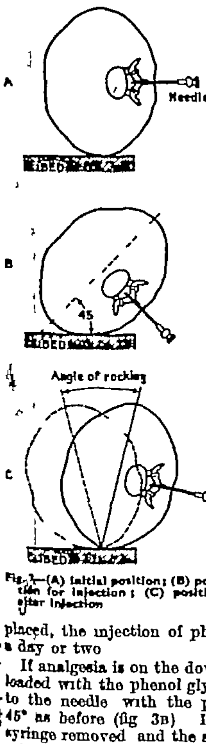

Fig. 3—(A) initial position; (B) position for injection; (C) position after injection

A preliminary test with nupercaine is made primarily to ensure that the needle is not directed upwards (fig 2 shows correct and incorrect positions) Using a 2 ml syringe 0 2–0 3 ml. of heavy nupercaine is slowly injected The patient is returned to the lateral lumbar puncture position, and rocked gently (fig 3C) Cutaneous sensory changes should appear on the patient's "lower" side sensory loss on the "upper" side means that the needle is directed too far upwards (fig 2) which would result in damage to the cord itself when the succeeding destructive agent is injected If the preliminary test shows that the needle is incorrectly placed, the injection of phenol should be postponed for a day or two

If analgesia is on the downward side the 2-ml syringe loaded with the phenol glycerin mixture is then applied to the needle with the patient rotated backwards at 45° as before (fig 3B) 1 3 ml is slowly injected, the syringe removed and the stylet inserted The patient is returned to the normal lateral lumbar puncture position and gently rotated backwards and forwards through this angle (fig 3C) Sensation must be tested immediately and if sensory loss is extending too far caudally the foot of the bed should immediately be held upwards by assistants to let the solution flow towards the cephalic end Conversely the head of the bed should be held up if sensory loss is spreading too high A further 0 5 ml of phenol mixture can be added if necessary

After the phenol has been injected the needle is left in situ for one hour If sensation returns even in the form of analgesia, pain will almost certainly also return before long In such circumstances the injection of gr $^{1}/_{100}$ silver nitrate dissolved in 1 ml. of glycerin, may successfully produce more permanent anaesthesia Intensification is obtained by adding 1 in 500 000 methyl sulphonal The effect of adding hyaluronidase is being investigated.

At the end of the procedure the patient can be gradually raised Plenty of fluids should be given and sedatives as required

Anæsthesia is at first widespread. In lumbar injections it often extends initially from lower abdomen to ankle but settles later to an area from groin to upper tibia It should overlap the pain area considerably If the anæsthesia is still present at the end of five days its effect is probably permanent and the patient should be allowed to go home but if necessary the phenol injection can be repeated after a few days

## Site of Injection

### *Pain of Pelvic Origin*

(*a*) Obturator and femoral distribution (groin, knee and thigh) Injection is made in the twelfth dorsal and first lumbar interspaces.

(*b*) Sciatic type Injection is made in the second or third lumbar interspace and the solution allowed to flow caudally by slight elevation of the head of the bed.

(*c*) Sacral pain (carcinoma of rectum) Injection is made in the fifth lumbar and first sacral interspaces with the patient sitting upright on a pillow and held backwards by assistants. A second or two after injection he is pulled forwards so that the solution can reach the lower sacral roots in the tip of the dural sac S 3 2 and 1 units can be covered in cases of lower sciatic involvement if when the tip of the dural sac is filled the patient is rotated on to his side quickly

### *Abdominal Pain from Carcinoma of Stomach Pancreas, &c*

Injection is made at the appropriate level—often sixth or seventh dorsal interspace—and repeated after a few days on the other side

### *Carcinoma of Lung*

Injection is made at a level corresponding to the pain and often at segments above and below

### *Brachial and Cervical Pain from Primary or Secondary Carcinoma*

Injection is at the fourth or fifth cervical interspace and the solution is allowed to flow caudally by gently raising the head of the bed. Alternatively it may be made at the second thoracic interspace and the solution allowed to flow in the opposite direction with the patient's head itself elevated as much as possible

After-effects are usually mild at most they consist of headache and vomiting which pass off in a few hours Brief aching in the affected area usually indicates success Paresis of the leg occurred in 3 out of 22 pelvic cases and was due largely to inexperience with the strength of the solution Urinary incontinence was a temporary complication in the rectal group Bedsores and burning have to be guarded against and the patient should as far as possible always lie on the sound side

## Results

The regions affected in the 37 patients treated with intrathecal injections of phenol were cervix (15 patients) rectum (5) genito urinary tract (2) stomach (2) brachial and cervical region (6) and lung (7) Results were based on the patients own statements on clinical observation, and on the reductions which it was subsequently possible to make in the dose of their analgesic drugs Of 19 successes now deceased 6 obtained almost complete relief right up to the time of death. The remainder were relieved to within a few days of their death The duration of relief varies 1 case of carcinoma of the rectum obtained seven months relief and several have been relieved for six months 8 of the 37 were apparently unrelieved ; 4 had carcinoma of the cervix 3 carcinoma of the bronchi and 1 carcinoma of the stomach

### Advantages

(1) The method is simple, and with care it can be carried out in any hospital For the patient it is a minor procedure

(2) A series of ganglia can be influenced by increasing the quantity of phenol injected, and by tilting the patient 3 patients were successfully given additional injections for involvement of new areas

(3) Alternative sites of injection can be used—e g, fourth and fifth cervical or second thoracic interspace, depending on whether the head or the foot of the bed is raised

(4) It can be used for cervical, dorsal, lumbar, or sacral units

(5) The method is safe, paresis, at the 1 in 18 strength, was slight On the other hand, retention often lasted three weeks in rectal cases

### Conclusion

At the time of injection the criterion for relief was a fixed anæsthesia over the pain area On this basis the cases were of two types

*Single nerve groups affected* (e g, obturator, sacral, or sciatic)

*Combined nerve groups affected* (e g, obturator plus sacral or obturator plus sciatic, and some cases of carcinoma of lung)

In the first type the pain was easily relieved In the second, however, it proved intractable Even with nupercaine the anæsthesia was either fleeting or entirely absent All were cases of advanced carcinoma, and in 6 the spine was involved. At necropsy 4 showed infiltration of the dura phenol could not reach the carcinoma encoated ganglia in these cases, but it did cause temporary anæsthesia of the emerging roots Thus the hypothesis of pain from perineural lymphatic invasion (Way 1951) might also apply to the ganglia and dura For uniform success, therefore, and since most cases follow the same pattern, a wide ganglion block should be carried out in the early stages of pain, before the growth has involved the ganglia

Finally, in three extreme cases of very advanced carcinoma "released phenol," made by adding 0 4 ml sterile water to 0 5 ml of 1 in 30 phenol in glycerin, was used, and produced anæsthesia from waist to feet Paralysis ensued in 1 case Further research is proceeding on the possibility of producing selective spinal cord block without causing motor weakness

### Summary

37 cases of incurable cancer were treated by intrathecal phenol Relief of pain was obtained in 29 cases

Success apparently depended on whether single or combined nerve groups were involved

Phenol in glycerin or propylene glycol was used with success at all spinal levels, including the cervical region

The immediate aim was to produce fixed skin anæsthesia over the painful area

Spinal cord block was attempted in 3 instances, and gave relief

My thanks are due to Dr Ralston Paterson (director) and Dr E C Easson, of the Christie Hospital and Holt Radium Institute, for referring patients to me, and to Dr and Mrs J Starkie and Mr F Young for their invaluable help

# CYCLOPROPANE, DENTAL EXTRACTION, AND SPARKS

J G Bourne
M A, M B Camb, F.F A R C S
ANÆSTHETIST ST THOMAS'S HOSPITAL, LONDON, AND SALISBURY HOSPITAL GROUP

H J V Morton
M A, M D Camb, F F A R C S
ANÆSTHETIST, HILLINGDON HOSPITAL, UXBRIDGE

THAT sparks might be thrown off when a forceps fractures the enamel of a tooth during its extraction was not foreseen when cyclopropane as an alternative to nitrous oxide anæsthesia was advocated by one of us (Bourne 1952, 1954a) Ignorance of this possibility seems to have been shared by others, and incredulity was expressed (Henry 1954) when Newton-Andrews (1954) reported that, while giving nitrous oxide, he had seen "a shower of sparks" plainly visible in a well-lighted surgery

Though this occurrence may have been singular it contra indicated the use of cyclopropane anæsthesia for dental extraction until the matter had been investigated (Bourne 1954b) The advantages of this method of anæsthesia and its successful trial over a period of years on more than 2000 patients prompted us to undertake such an investigation We report here our investigation and suggest a simple safeguard

### Method

" Enamel, the hardest substance produced in the body sparks with steel like flint" (Cowdry 1944) This fact can be easily demonstrated We have obtained sparks, visible in daylight, by the application of dental forceps, made either of stainless or plated steel, to the crowns of extracted teeth, whether deciduous or permanent, whether molar, premolar, canine, or incisor, whether healthy or cavitated, whether filled or unfilled, and whether dry or wet with saliva and blood (After a few applications the plating becomes erased from the biting surface of plated forceps, exposing the steel )

The best display of sparks was obtained when fine root forceps were strongly applied to the crowns of healthy molar teeth and then were made to fracture the enamel Though this manœuvre would seldom, if ever, be used in clinical practice it was the one used in experiments 1 and 2 (fig 1)

*Experiment 1 Influence of Oxygen on Sparking*

In an atmosphere of carbon dioxide (which does not support combustion) sparks, viewed in the dark, appeared only as the slightest local redness Occasionally a dull red particle was thrown off about an inch In air (21% oxygen) the sparks were orange red and were often seen to fly a foot or more When oxygen was added to air, the number and brilliance of the sparks increased In pure oxygen a shower of white sparks was obtained at almost every trial and with the greatest ease

*Experiment 2 Influence of Oxygen on Ignition*

In this experiment we tested the ability of sparks produced with forceps and teeth to ignite various mixtures of cyclopropane, oxygen and nitrogen passing through a semitransparent rubber tube The apparatus used is shown in fig 1 The gas flows were measured by rotameters, checked, and, where necessary, recalibrated with a Parkinson and Cowan gas meter The composition of the resulting mixtures was further confirmed by analysis by the method referred to below

The tooth and forceps were manipulated by hand through the rubber (fig 1) Owing to the imperfect transparency of this rubber only bright sparks were visible, even in the dark. These alone were taken into account in the results shown in the accompanying table With the lower proportions of oxygen the cyclopropane concentration was adjusted to give mixtures which, according to Guest et al (1952), were most easily ignited by an electric spark The inflammability of each mixture that failed to be ignited by sparks from teeth

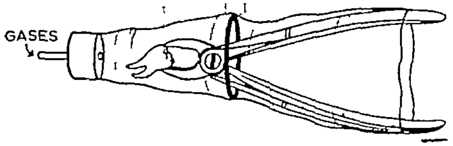

Fig 1—Apparatus for testing ignition of gas mixtures by sparks produced with dental forceps and teeth. The gases comprising the mixtures were led to the apparatus through separate tubes.

and forceps was confirmed by igniting it with an induction coil spark from electrodes passed into the apparatus

*Experiment 3 Ignition with Sparks from Dental Forceps and Grindstone*

A dental forceps applied to a grindstone driven at high speed by an electric motor gives off a stream of sparks apparently in every respect far in excess of any that can be obtained with teeth As expected this was found to be a more effective means of ignition than was striking sparks with teeth. In this experiment the same apparatus was used as in experiment 2 except that the forceps and tooth were dispensed with and the end of the tubing which in experiment 2 gripped the forceps handles, was now held open The stream of grindstone sparks, directed through the opening passed down the tubing to the end at which the gases were being delivered

With this arrangement the mixtures listed in the table down to and including that which contained 28% oxygen were ignited at once The mixture, however which contained 25% oxygen, and other mixtures, not listed, with still less oxygen could not be ignited. Nor with 25% oxygen, could mixtures in which the cyclopropane concentration was varied throughout the whole of its ignitable range be ignited by this method though all of them were instantly ignited, during each test, by induction-coil sparks.

*Experiment 4 Ignition of Cyclopropane in Nitrous Oxide*

Using the grindstone method we were able to ignite a mixture consisting of 10% cyclopropane and 90% nitrous oxide 10% cyclopropane in other mixtures in which oxygen was added at the expense of nitrous oxide were also ignited.

INFLUENCE OF OXYGEN ON IGNITION OF CYCLOPROPANE BY SPARKS FROM TEETH AND FORCEPS

| Cyclopropane (%) | Oxygen (%) | Nitrogen (%) | Ignited by sparks from teeth and forceps | No of times sparks seen before ignition |
|---|---|---|---|---|
| 20 | 80 | | Yes | 0 |
| 35 | 65 | | Yes | 0 |
| 45 | 55 | | Yes | 9 |
| 15 | 60 | 25 | Yes | 4 |
| 16 | 40 | 44 | Yes | 50 |
| 9 | 34 | 57 | Yes | 10 |
| 8 | 30 | 62 | Not with 100 sparks | |
| 8 | 28 | 61 | (Not tested) | - |
| 8 | 25 | 67 | Not with 100 sparks | |

*Experiment 5 Ignition of Ether and Divinyl Ether (Vinesthene)*

The vapour of each of these agents in oxygen was ignited with the greatest of ease by sparks from teeth A mixture containing nitrous oxide and oxygen at flow rates of 6 litres and 2 litres respectively which had passed over ether in a bottle was ignited at once by grindstone sparks.

The results of our first three experiments suggested that should sparks such as we have produced experimentally be formed during the extraction of teeth when cyclopropane had been administered, the likelihood of an explosion resulting would depend mainly on the concentration of oxygen present in the mouth at the time To carry the investigation further therefore it was necessary to anæsthetise patients by the method under review and to measure the proportion of oxygen in the exhaled gases This method of anæsthesia described by Bourne (1954a) is as follows

A rubber bag of about 6 litres capacity is filled with cyclopropane and oxygen in equal parts. The bag is connected to a face piece by a two-way stopcock The stopcock shuts off the bag and leaves open an aperture through which air is breathed while the face piece is being adjusted over the patient's mouth and nose When this has been done the stopcock is turned, closing the air aperture and allowing the patient to breathe in and out of the bag At the end of the administration the whole apparatus is removed from the face and the extractions are undertaken

It was recommended by Bourne that the administration should be continued for about a minute but since we found that the amount of oxygen in patients' exhalations increased a little when the administration was prolonged in the 13 patients we have examined we continued it for two or three minutes so that the oxygen would reach the highest levels possible

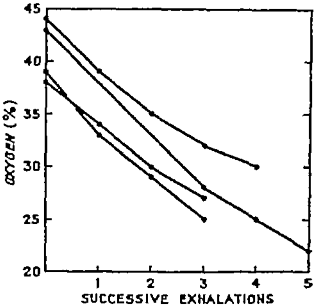

Fig. 2—Concentration of oxygen in successive exhalations of 4 patients breathing air after withdrawal of anæsthetic mixture (cyclopropane 50% with oxygen 50%)

From this description it will be realised that with this method of anæsthesia sparks could be struck only after the anæsthetic had been withdrawn and only during an exhalation might the patient be in danger from an explosion due to this cause We therefore analysed exhalations for their oxygen content

### Measurement of Oxygen in Patient's Exhalations

The samples of exhalations were drawn into syringes through needles passed through a rubber diaphragm in a specially prepared face piece The first sample was taken just before the end of the administration At the end of the administration the anæsthetic was withdrawn by turning back the stopcock so that the bag was shut off The patient then breathed air through the aperture while the face piece was retained on his face In this way we were able to continue to sample the exhalations from under the face piece after known numbers of inhalations of air

*Cyclopropane 50% with Oxygen 50%*

Of the 13 patients examined 7 were children, the youngest being aged 3 years The oldest adult was aged 82 Since in clinical work some error in adjusting the flow rates of the gases occurred the contents of the bag were analysed before each administration It was found that the oxygen varied between 40% and 54% The results of this experiment are presented in fig 2, which shows the values we obtained in 4 of these patients including the 1 who gave the highest values Usually as expected higher values were found in children than in adults.

*Cyclopropane 50% with Oxygen 25% and Nitrogen 25%*

A further series of 13 patients were anæsthetised in exactly the same way as those in the foregoing experiment and just before the anæsthetic was withdrawn their exhalations were sampled In these patients, however 50% cyclopropane was administered not with oxygen but with oxygen and nitrogen in equal parts delivered from a cylinder containing the mixture (At flow rates of 750–1500 c.cm per minute the oxygen nitrogen mixture can be measured with sufficient accuracy through an oxygen rotameter ) As in the previous experiment and for the reason there given the contents of the bag were analysed shortly before each administration On one occasion they were found to consist of 42% cyclopropane and 29% each of oxygen and nitrogen The oxygen in fact varied between 25% and 29%. We found that in none of these patients did the oxygen concentration in any exhalation rise above 23%

*Analysis of Samples of Gas* ,

The gases were analysed by a method based on Guthrie's (1921) apparatus for the analysis of air The samples were passed directly into the capillary tubes of each of three absorbing vessels in series The first contained concentrated sulphuric acid, the second sodium hydroxide, and the third an oxygen absorbing solution These absorbed cyclopropane, carbon dioxide, and oxygen in turn As a measure of the accuracy of this method 10 analyses of air gave a mean oxygen percentage of 20 5% with a range of ±0 5%

## Discussion

The energy required to ignite cyclopropane oxygen nitrogen mixtures is inversely proportional to the concentration of oxygen and directly proportional to that of nitrogen This has been shown precisely by Guest et al (1952) using electrical energy Our findings with sparks from forceps showed a similar trend Furthermore, it seems probable from experiment 2 that the effectiveness of sparks from forceps, considered as a source of ignition, decreases with decreasing oxygen If this is so, there are two influences both of which (should sparks be formed during the extraction of teeth) would make an explosion less likely when the oxygen is low than when it is high

From our experiments we feel justified in concluding that the ignition of cyclopropane by sparks produced with forceps and teeth during extractions is unlikely when the concentration of oxygen in the mouth does not exceed 30%, and is improbable in the extreme when the concentration is 25% or lower

The oxygen concentration in the exhalations of patients anæsthetised with 50% cyclopropane with 50% oxygen decreased to 25% only after a few breaths of air had been taken During these few breaths, therefore, it would be wise to consider patients at risk from an explosion

It might be thought that this danger could be avoided by asking the dental surgeon to wait until these breaths had been taken But in our view this could not be relied on, since dental surgeons are wont not to pause at this stage Or, again, it might be thought that the formation, during an extraction in normal clinical practice, of the sparks reported by Newton-Andrews (1954) was unique, and therefore this danger could be altogether ignored Certainly the manœuvres we used to produce sparks experimentally were quite unlike any that might be used in practice Nevertheless we believe that, under certain conditions, sparks could be produced During the extraction, for example, of an upper molar tooth with a cervical cavity on the lingual side and with buccal and palatine roots inclined steeply away from one another, forceps tend to slip downwards towards the crown and may fracture the edge of the cavity After several trials with extracted teeth we produced sparks in this way We have produced sparks also when teeth simply broke, an accident which we have often seen in practice Moreover, though sparks formed in clinical practice have not, so far as we are aware, been reported before the communication of Newton Andrews, possibly they may have been produced but went unnoticed under normal lighting conditions On the other hand, it might be argued that the risk is no less with ether or divinyl ether given with a large concentration of oxygen—a practice that, with divinyl ether at any rate, has been current for many years without, so far as we know, there having been reported an explosion caused in this way

We conclude that, when cyclopropane, divinyl ether, or ether is administered with a large concentration of oxygen, the patient is momentarily at risk if extractions are made immediately after the mask has been removed We th[illegible]re suggest that cyclopropane should be used n[illegible]gen but with a mixture of oxygen and nitrogen in equal parts Cylinders of this oxygen-nitrogen mixture for medical use are readily available commercially We have administered 50% cyclopropane with this oxygen-nitrogen mixture with results that were clinically indistinguishable from those we obtained when 50% cyclopropane was used with 50% oxygen In 13 patients examined the concentration of oxygen in the exhalations did not then increase above 23%

In conclusion, though detailed comment is outside the scope of this report, we draw attention to the fact that, when inflammable agents are used, the hazard we have investigated is probably, in any case, smaller than that from static sparks Needless to say, therefore, precautions, which are now well known, should always be taken to avoid this latter danger

## Summary

Enamel, the hardest substance in the body, like flint, gives sparks with steel

Experimentally we have produced sparks, visible in daylight, with teeth and dental forceps

The number and brilliance of these sparks increased with increasing oxygen in the surrounding atmosphere.

With these sparks we ignited cyclopropane in oxygen With decreasing concentrations of oxygen ignition became increasingly difficult When the concentration of oxygen was as low as 30% we failed in a hundred consecutive attempts, at each of which good sparks were seen

With sparks from teeth and dental forceps we ignited with great ease the vapour both of ether and of divinyl ether in oxygen

A grindstone applied to dental forceps threw off a stream of sparks far in excess of any that could be obtained with teeth With these sparks we ignited cyclopropane oxygen-nitrogen mixtures with concentrations of oxygen as low as 28% but failed to ignite cyclopropane throughout its entire inflammable range with concentrations of oxygen that were 25% or less

We concluded that, when cyclopropane is used, patients should be considered to be at risk from an explosion due to sparks from dental forceps and teeth if the oxygen in their exhalations exceeds 25%

The concentration of oxygen in the exhalations of 13 patients anæsthetised with 50% cyclopropane in 50% oxygen by the method described by Bourne (1954a) was measured It did not decrease to 25% until several breaths of air had been taken

We suggest that, as a safeguard, 50% cyclopropane should be administered not with oxygen but with oxygen and nitrogen delivered from a cylinder containing these two gases mixed in equal parts Such cylinders for medical use can be readily obtained commercially The flow rate of the oxygen nitrogen mixture can be measured with sufficient accuracy with an oxygen rotameter

With this mixture anæsthesia was clinically indistinguishable from that which we obtained when cyclopropane was used with 50% oxygen, and in 13 patients examined the concentration of oxygen in the exhalations did not increase above 23%

We wish to thank Miss I M Young, lecturer in physiology, Sherrington School of Physiology, St Thomas's Hospital, and Mr N Thurlow, senior technician there, for suggesting the method of gas analysis and for their helpful advice in its use

E BECK
RESEARCH ASSISTANT NEUROPATHOLOGICAL DEPARTMENT INSTITUTE OF PSYCHIATRY MAUDSLEY HOSPITAL, LONDON

FOR most of the mentally ill patients who come into the neurosurgeons hands a restricted leucotomy or topectomy is now the operation of choice

Clearly preferences for different forms of leucotomy should ultimately depend on a large series of detailed clinicopathological correlations but not enough of such material is available. In these circumstances the publication of a single clinicopathological study is justified Not only will it make a small contribution to the evidence available for a later analysis but the difficulties of interpretation which become apparent when the clinicopathological correlations are discussed may usefully draw attention to those deficiencies in our present knowledge which most require investigation

Careful analysis of published cases does not provide evidence sufficient to sustain the widespread and enthusiastic belief that a bimedial inferior cut is always the modified operation of choice In this operation the section of the white fibres is in the usual plane but is limited as far as possible to the ventromedial quadrant of each lobe It is sometimes called an orbital leucotomy Further in the present case full recovery from a *non-psychotic* mental illness followed a leucotomy in which these ventromedial segments virtually escaped damage The clinical findings suggest that the improvement in this patient depended on personality changes These were of a type which, in other patients might bear no causal relationship to therapeutic success In such patients they would be an irrelevant defect in the present case, it is argued they were essential to recovery

### Case report

A married woman aged 59 diagnosed as suffering from (i) tinnitus due to middle-ear disease, and (ii) a hypochondriasis with hysterical features, complained mainly of terrible head noises, palpitation, and weakness of the legs.

*Family History*—Her father was an alcoholic who terrorised the family while in his cups The only other child her elder brother was described as obsessional and eccentric. He was discharged from the Navy with neurasthenia and has at times drunk to excess. She had one adult daughter who like the patient s mother was not known to be abnormal

*Personal History*—At the age of 4 she had measles followed by double pneumonia Subsequently she was a fragile nervous, and sensitive girl who was terrified of her father s alcoholic bouts For 12 years she worked as a lady s maid and at the age of 30 she married her childhood sweetheart a chauffeur Her married life had been happy After the birth of her daughter she underwent appendicectomy and nephropexy Otherwise she had been well

*Personality*—The patient described herself as always rather pessimistic but her husband characterised her as " rather a spark and it seemed that she had been capable and hard working but nevertheless full of life and gaiety Although an extremely active woman who was always bottling preserving and knitting she was inclined to be excessively anxious over small matters and would arrive over early for trains. She was meticulous with her clothes and fussy about the house and would get upset if her routine were put out Liable to headaches she was careful of her health. She had few interests outside her home and family and her friends were chiefly those of her youth Gardening singing and sketching were her hobbies

*Present Illness*—At the age of 25 an attack of flu left her with a ringing noise in the head mainly in the left ear This noise gradually lost its intensity and after a time became so faint that she could only hear it if she especially listened for it. 27 years later at the age of 52 she had an attack of gastric flu with diarrhœa and vomiting and after this the noises increased in intensity They became worse and 4 years later were intolerable

*On admission* she described them as varying—sometimes like the reverberations of beaten iron, at others like clanging cymbals or the dragging of heavy chains. Often the noises were so loud that she could feel something hitting the inside of her head which at times seemed to be jerked about For a year or two she had felt weak, lifeless, and depressed with the result that she could not attend to her normal household duties. Her legs were weak and tremulous Palpitations were accompanied by a dreadful pain in the chest Although she was constipated her appetite remained good

*On examination* she was well nourished neat and self composed She told her story with a wealth of circumstantial detail and the house-officer noted that her mood was characterised by complacency rather than severe depression or emotional distress Physically apart from a chronic lesion of the right inner ear there was no evidence of organic disease of the nervous system She had hypertension (blood pressure 250/130 mm Hg) and arteriosclerosis.

*Operation*—On Nov 12 1948 Mr Harvey Jackson carried out a standard prefrontal leucotomy

*Postoperative State*—Immediately after the operation the patient was grossly confused. She had urgency and incontinence Her confusional state resolved rapidly and after a short convalescence she returned home much less worried by her noises but distinctly apathetic

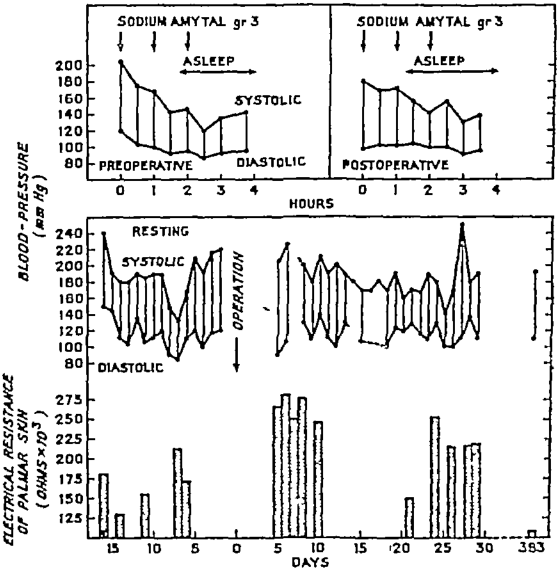

Fig 1—Blood-pressure at rest and under sodium-amytal sedation and electrical resistance of palmar skin before and after leucotomy

*Follow-up*—3 months after the operation a home visit disclosed that she was more alive and interested She was using make up again and planning her future wardrobe in a sensible manner Only once had she been incontinent, but she had been troubled by some urgency Her husband and her daughter were both very pleased with her progress, finding her unworried and placid but very lazy She was helping little with household tasks and mostly sat about doing nothing She had done some shopping in a competent manner, but she herself noticed that she was 'slower on the uptake," and her daughter found her distinctly forgetful Her appetite was excessive A year after the operation her husband reported that she was still improving She concentrated better and was taking the initiative in such matters as altering her own clothes and mending her husband's Her cooking was good but plainer, and she still occasionally forgot to put salt in the potatoes She found it difficult, moreover, if she was put out of her routine—e g , if someone extra came to a meal, or if her daughter tried to persuade her to try a new recipe She enjoyed going out more than she had done for the past 6 or 7 years, but in the cinema she became lost if the plot was complex Of her tinnitus she said "I have those noises but I can't be bothered with them" Her husband thought that her personality was improved and she was not an invalid in any way "If she could sleep more and eat less, she would be no problem at all" 6 months later she was still happy go lucky, did not appear to bother about anything, and when warned by her husband about leaving her bag in the shops she replied "If I lose it I lose it" In June, 1950, she had what was probably a small cerebrovascular accident, which was followed by an increase in her apathy and a further impairment of her powers of memory and concentration In December, 1952, she died of cardiac rupture

*Electro encephalography*—Before the operation the electro encephalogram was symmetrical, with a normal alpha rhythm The record was dominated by a generalised high voltage rhythm of 20 cycles per sec Twenty days after the operation distinct changes were observed The alpha rhythm at 10–11 cycles per sec was of greater amplitude and spread further forward The fast rhythm of 20 cycles per sec was no longer apparent but may have been masked Irregular slow activity of 1–3 cycles per sec was seen bilaterally in the prefrontal regions but was much more extensive on the right, where it was seen as a focus A year after the operation the only abnormality was a small amount of low voltage slow activity in the frontal regions, now greater on the left than on the right 4 years after the operation (Nov 6, 1952) the frontal slow activity was only just discernible, but the record showed a new abnormality a bilateral theta rhythm at about 7–8 cycles per sec predominantly in the left frontotemporal area There were also, on over breathing, suggestions of spikes in the left frontotemporal region

*Psychological Tests*—The patient was tested with the Wechsler Bellevue scale before the operation and 1 4, 10 and 48 months after it She scored an intelligence quotient of 110 before the operation and her results showed no significant evidence of intellectual deterioration A month after the operation there was clear evidence of intellectual impairment Her scores on all subtests except picture completion, similarities, and block design showed not only no practice effect but even a definite loss T[illegible] was most evident on the pic[illegible]ement, digit span, and digit symbol substitution subtests 3 months later her performance had definitely improved, but 19 months after the operation it was still below her preoperative level 4 years after the operation there was evidence that further deterioration had taken place Her performance on all subtests was consistently below what it had been before the operation she could not reproduce the Terman designs, her performance at Weigl's sorting test was poor, and she failed to learn the Babcock sentence after nine attempts

*Autonomic Functions*—On admission her blood pressure was 250/130 mm. Hg Her *urine* was normal, *blood-urea* 40 mg per 100 ml , and *urea clearance* 102% *Intravenous pyelography* revealed no functional or anatomical abnormality Her *heart* showed some left ventricular enlargement The blood pressure was recorded morning and evening in the right arm Though the evening values tended to be higher than the morning values, leucotomy affected both in a similar manner, and only the evening values are presented here (fig 1) It will be seen that there was no pronounced fall in either the systolic or diastolic pressures even in the immediate postoperative period A year after the operation (Nov 30, 1949) the patient's blood pressure was recorded in the outpatient department It was then 220/125 mm Hg After 15 minutes' rest the mean of three readings was 192/112 mm. Hg In November, 1952, the blood pressure was 230/125 mm. Hg These values were essentially the same as those found preoperatively In addition to the resting blood pressure observations 'Sodium amytal' sedation tests were done both before and after operation The results of these are given

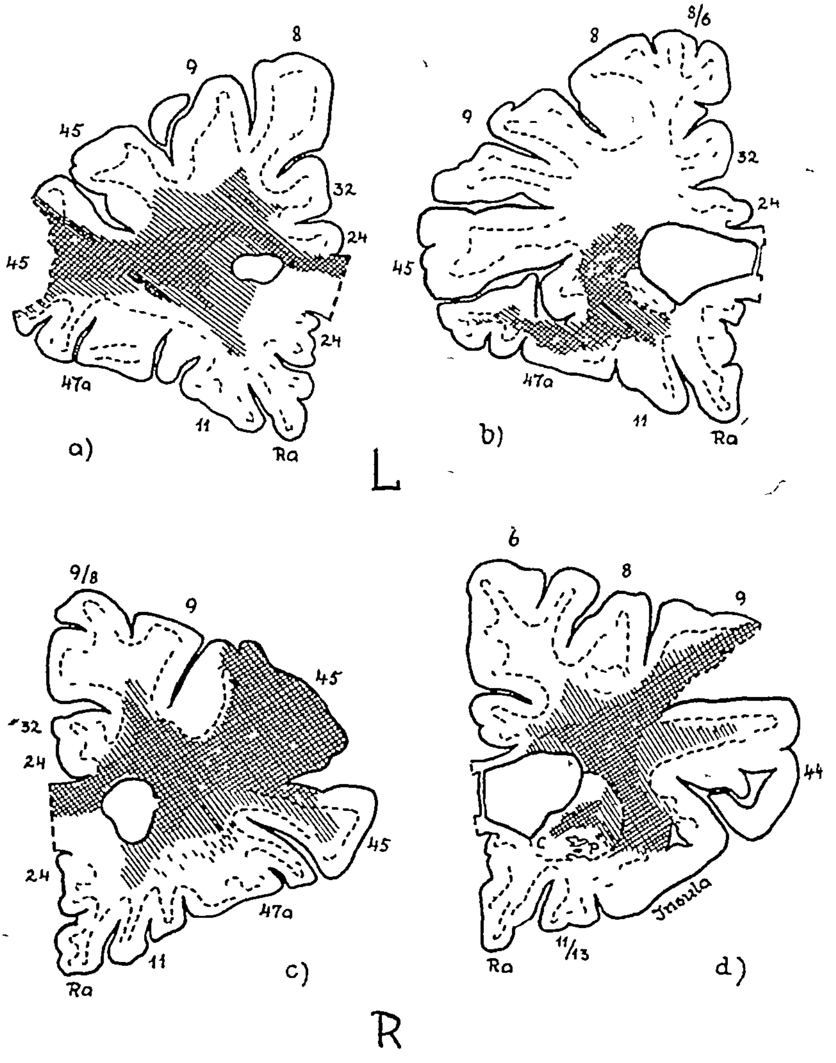

Fig 2—Greatest extent of surgical lesion in frontal lobes (hatched areas) Numerals indicate Brodmann s cyto-architectonic fields in each section C, caudate nucleus ; P putamen Ra, area recta anterior

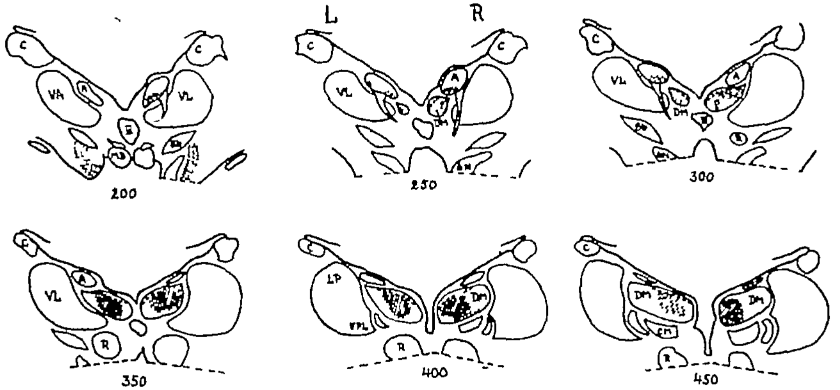

Fig. 3—Retrograde degeneration in thalamus (hatched areas): A, nucleus anterior thalami; C, nucleus caudatus; DM, nucleus medialis dorsalis thalami; LP, nucleus lateralis posterior thalami; MB, corpus mammillare; R, nucleus ruber; Sb, corpus subthalamicum; SN, substantia nigra; VA, nucleus ventralis anterior thalami; VL, nucleus ventralis lateralis thalami; VPL, nucleus ventralis posterolateralis thalami; III, ventriculus tertius.

graphically in fig. 1. In the second test, 29 days after the operation, the fall in both systolic and diastolic pressures was much less than preoperatively, the initial readings being much lower and the lowest reading very slightly higher. The *resistance of the palmar skin* was measured on several occasions before and after the operation. This technique has been described elsewhere together with the results obtained with patients undergoing prefrontal leucotomy (Elithorn et al. 1954). Recordings were made from both hands. No consistent difference between the two hands was observed, and in fig. 1 the mean values for the two hands are given. It is apparent that all except one of the immediately postoperative values are higher than those found before the operation. The postoperative reduction in palmar sweating which generally follows prefrontal leucotomy has been shown to be independent of thermoregulatory requirements. It is probably related to the relief of anxiety which normally follows the operation. After the operation there was a considerable change in *weight*. In February, 1949, the patient weighed 9 st. $7^1/_2$ lb.; 2 years later she weighed 13 st. 5 lb. Strenuous attempts were made to keep her to a diet, and her weight fell to 11 st. 10 lb. On her last visit, in November, 1952, she weighed 11 st. $4^3/_4$ lb. Throughout the follow-up period she continued to complain of *insomnia*, which, however, was adequately controlled with hypnotics.

*Pathology*.—The brain weighed 1430 g. and showed considerable atheroma of all the arteries at the base, especially the vertebral, basilar, and carotid arteries. There was a slight bilateral tonsillar pressure cone. Both frontal lobes, particularly on their anterior and dorsal aspects, were somewhat atrophic. The leucotomy entry marks were in the pars triangularis of the inferior frontal convolution on either side. A coronal section through these entry marks at the level of the genu corporis callosi passed through the greatest extent of the leucotomy scar (fig. 2*a* and *c*). This occupied almost the entire white matter of both frontal lobes, extending to the wall of the lateral ventricle, which was pierced on the right side; the two scars communicated through the dorsal half of the corpus callosum. Only the most medial dorsal and orbital regions had escaped. The cortex of both inferior frontal convolutions was extensively damaged. More posteriorly, at the level of the head of the caudate nucleus, the lesion in the left hemisphere (fig. 2*b*) was much smaller and terminated in a central and ventral position, slightly involving the caudate nucleus. The lesion in the right hemisphere at this level (fig. 2*d*) was still extensive and occupied, in addition to those structures mentioned above, parts of the striatum, the claustrum, and the capsulæ externa and extrema. It terminated 5 mm. further posteriorly in a similar position. Anteriorly the lesions extended within the central white matter to the level of the pregenual gyrus cinguli on either side. Histological investigation of serial sections through the thalamus (fig. 3) showed substantial retrograde degeneration in both dorsomedial nuclei (the right more than the left), moderate degeneration in the right anterior nucleus, and slight changes in the left anterior nucleus. There was considerable nerve-cell loss, shrinkage, and a dense compensatory gliosis. From the site of the degeneration within the thalamic nuclei and from the histological investigation of the surgical lesions one can conclude that the thalamic connections with Brodmann's areas 8, 9, 10, 46, 45, 47, lateral 11, and 24 were severed. All these areas were more severely involved on the right side than on the left. Further, a few fibres to the left medial orbital gyrus rectus were interrupted. In addition to the thalamofrontal projection, the fasciculus cinguli, the superior longitudinal and uncinate fasciculi, and Arnold's bundle were cut bilaterally. Representative blocks from various cortical regions showed no gross damage but some increase of the marginal glia and of the fibrous glia in the white matter. Most blood-vessels, both of the brain and the meninges, showed adventitial fibrosis; the larger and medium-sized arteries showed various degrees of arteriosclerosis.

## Discussion

In view of the current preference for selective "bimedial" incisions this case is of considerable interest. It is clear that the operation aborted a severe hypochondriasis occurring at the involutional age. Pathological investigation has shown that this result was achieved in the absence of significant damage to, or involvement of, the medial orbital regions, and with only unilateral involvement of the cingulate areas. In the light of these findings it seems worth while to examine the evidence on which the current preference for bimedial operations is based. In doing so it becomes necessary to consider whether an operation which produces statistically "maximal improvement with minimal personality change" is necessarily the operation of choice in any given patient.

Much of the enthusiasm for the bimedial operation stems from the results of the Massachusetts lobotomy studies (Greenblatt and Solomon 1952). These workers have in fact only shown that in *schizophrenics* this operation produces results which are more satisfactory than either a standard bilateral operation or a unilateral one. They do not themselves provide any evidence on which the different symmetrical modified cuts can be compared. Their original preference for this operation is perhaps based on the earlier work of Scoville et al. (1951), who reported the results obtained in an [illegible] tigation which compared the effects of three [illegible] undercuts, superior medial cingul [illegible]

These workers, the majority of whose patients were also *schizophrenic*, concluded that there was little to choose between the three areas from the point of view of therapeutic effect, but claimed that there were definite differences between the postoperative syndromes characteristic of each area The superior-convexity operation, they stated, was associated with the most striking personality changes, in particular emotional blunting and apathy After an orbital cut the personality showed less change, this being in the direction of hyperactivity and restlessness Medial cingulate operations they reported as causing postoperatively a severe physical "knock out," again with little personality change These results contrast strongly with those of Le Beau (1952), whose patients also underwent various forms of topectomy and undercutting Le Beau agrees that operations on the convexity tend to produce the greatest personality change, in his cases, however, this was in the direction of overactivity—"the hypomanic syndrome of the convexity"—whereas orbital cuts produced apathy

Similar inconclusive findings have also been reported after clinicopathological investigations Thus, reviewing the results obtained from their study at the Institute of Psychiatry, Meyer and Beck (1954) conclude

> "The dorsal and, in particular, the dorso lateral sectors of white matter do not appear to be as significant for improvement as the midcentral, orbital and cingulate sectors On the other hand, involvement of the dorso lateral and lateral white matter, and particularly cortex, appears to be one of the factors responsible for severe personality change" However, they point out that "full social recovery was obtained provided the cut was quantitatively adequate without consistent involvement of medial, orbital, and cingular segments"

Eie (1954) reports the macroscopic necropsy findings in 29 cases and claims that his results show that

> "aggressive, hyperactive, restless patients may improve after lesions limited to the connections of the granular areas of the convexity and of the cingulate gyrus"

One important difference between various workers is that the selection of patients differs widely from one investigation to another Both pathological investigations were undertaken largely on patients who died in mental hospitals The Maudsley material was diagnostically mixed, whereas those of Eie's patients who were suitable for clinicopathological analysis were all overactive and aggressive before operation In the two clinical series discussed the contrast is even greater most of Scoville's patients were *schizophrenics*, whereas most of Le Beau's were operated on for *intractable pain*

The striking contradictions between the results found by these and other workers suggest that ablations of anatomically corresponding areas need not produce similar defects in different patients Indeed, most clinicians will agree that their expectations of the sort of defects which may follow any individual leucotomy are coloured by the previous personality of the patient

The conception that there exists an operation which will produce the greatest improvement together with the smallest personality change is based on the belief that improvement and personality change are two independent variables On theoretical grounds, and these are supported by clinical observations—in particular Partridge's (1949) important observations on depressive illnesses treated by leucotomy—it may be presumed that two major effects may be expected from frontal ablations

(1) Such a lesion may abort a functional psychosis (e g , an endogenous depressive illness) which in other circumstances might be expected to resolve spontaneously or to be resolved by treatment (e g , electric shock) For this effect the surgeon would seek to damage the area which would produce the greatest "shock" effect together with the smallest persisting disturbance of personality and intellect

(2) The main effect of a prefrontal ablation is to produce of personality which is generally characterised by a reduction in anticipatory and preoccupative activity Such a change, if not too extensive, may sometimes be in all ways beneficial, and is then sought deliberately in the surgical treatment of psychoneurotic disturbances of personality In other cases it might be necessary to produce these changes to an excessive degree so that a diminished personality should react with less emotional disturbance to an otherwise intolerable *strain*—e g , excessive *pain*, and the experiences of a schizophrenic psychosis (Frankl and Mayer Gross 1947) The surgeon seeking to obtain solely an alteration in personality structure would wish to cause the least structural damage compatible with achieving the desired effect—i e , he would choose to operate on the region known to be most likely to produce the type of personality alteration which was desired

Applying this type of analysis to the present clinicopathological case report one may argue that the successful results were closely associated with, and dependent on, the alterations in personality which followed the operation There was in the history and on examination little evidence that the illness might be an endogenous depressive one Although the onset was during the involutional period and followed a minor physical illness, there was no diurnal variation of symptoms, no retardation, and no objective sign of depression The clinical picture was essentially one of preoccupation with, and elaboration of, a disturbance of sensation It can be explained most economically as a reactive development of the patient's premorbid personality tendency to anxious preoccupation of the obsessional type This excessive reaction may perhaps have been partly precipitated by arteriolar and psychological stresses associated with the involutional period The changes in personality which followed leucotomy, and which justifiably came to be characterised as defects—i e , her laziness, her placidity and her lack of concern for herself, her property, and her relations—can be seen as a reduction in her tendency to ruminative and anxious preoccupation. Two main qualitative differences between her bothering less about her symptoms and her bothering less about her cooking and her finances seem to be (1) that the stimulus of the tinnitus was always present, and (2) that taking thought about the noises would not reduce their intensity Failure to habituate to a constant and irreducible source of emotional distress is characteristic of the neurotic personality and especially of the obsessional neurotic It is therefore likely that the change of personality involving a reduction in preoccupative anxiety was essential to the success of this operation, and that this personality change was undesirable only in so far as it was excessive

As regards the involvement of the orbital and cingulate regions, it appears that, since the operation was both successful and excessive, a further extension of the lesion would only have increased the defects To have cut the orbital and cingulate sections in place of an equal amount of dorsal tissue would (according to most workers) have produced less personality change But (most authorities would again agree) a similar effect would have been produced more economically by reducing the amount of dorsal tissue cut Later experience with modified leucotomies in non psychotic patients crippled by a morbid preoccupation with a tinnitus has in fact shown that operations restricted to the convexity, as well as bimedial cuts can produce relief with only minor personality changes These changes may in their own right be regarded by close relations as beneficial (Elithorn 1953)

We may conclude that the search for an operation which is statistically most satisfactory for all patients is sterile Both the relevant published reports and the analysis of the present clinicopathological report support Fulton's (1951) contention that restricted leucotomies should be adapted "to the nature of the mental illness" Fulton suggests that depressed patients should have the bimedial type of operation, and that those who are overactive or agitated might benefit most from a dorsal topectomy It is only necessary to point out that a causal clinical analysis is more important and relevant than an *observational correlation* which will depend on the sample of patients examined Many patients are agitated and overactive because they have a "depressive" illness

## Summary

The clinical history of a patient incapacitated by preoccupation with severe tinnitus and who was treated successfully by a 'standard' prefrontal leucotomy is reported together with a description of the primary lesions and the retrograde degeneration in the thalamic nuclei

The concept that there is a single selective operation which will provide in each case the greatest improvement with the smallest personality change is dismissed as unlikely

The relative rôles of 'improvement' and "personality change" in producing a satisfactory therapeutic result are discussed

We are particularly indebted to Dr Eliot Slater and Mr Harvey Jackson under whose care this patient was, and we would also like to thank Dr E A. Carmichael and Prof A Meyer for encouragement and advice Miss M. A Crosskey assisted with the autonomic investigations We are also indebted to Dr W A Cobb and Prof O L. Zangwill in whose departments the electro-encephalographic and psychological studies were made

# Preliminary Communication

## BLOOD CONCENTRATIONS OF PYRUVIC AND α-KETOGLUTARIC ACIDS IN NORMAL PEOPLE AND DIABETIC PATIENTS

THE blood levels of α keto acids in patients with diabetes mellitus have attracted interest in recent years with the development of more specific and accurate methods for determining these important metabolites Villano[1] claimed that the blood concentrations of pyruvic and α ketoglutaric acids were greatly increased in diabetes but other workers[2 3] have reported raised blood levels of the two acids in only about half their patients, and Von Marken and Florijn[4] stated that the blood pyruvate level was normal in diabetic coma Conflicting results have also been obtained with animals Fidanza and Laviano[5] reported increased blood α ketoglutarate levels in alloxan diabetic rats whereas Frohman et al[6] observed that the tissues of alloxan-diabetic rats possessed a normal content of pyruvic acid but decreased levels of α ketoglutaric acid

The methods used have usually been based on the formation and subsequent separation by paper-chromatography of the 2 : 4 dinitrophenylhydrazone derivatives of the α keto acids. However 2 4 dinitrophenyl hydrazine is not a completely satisfactory reagent for this purpose because it is not specific for the α keto acid grouping and also because the derivatives tend to give rise to multiple spots during paper-chromatography from separation of geometrical isomerides[7] The first objection is of particular relevance when specimens from diabetic patients with ketosis are examined, because interference from aceto-acetic acid may occur when high concentrations of this substance are present[8]

BLOOD CONCENTRATIONS OF PYRUVATE, α KETOGLUTARATE AND GLUCOSE IN NORMAL AND DIABETIC SUBJECTS (MG PER 100 ML.)

| — | | Pyruvate | α-keto glutarate | Glucose |
|---|---|---|---|---|
| Diabetic patients (8) | 1 | 0·35 | 0·14 | 200 |
| | 2 | 0·33 | 0·06 | 91 |
| | 3 | 0·50 | 0·10 | 208 |
| | 4 | 0·31 | 0·05 | 250 |
| | 5 | 0·13 | 0·10 | 124 |
| | 6 | 0·20 | 0·08 | 350 |
| | 7 | 0·44 | 0·07 | 190 |
| | 8 | 0·86 | 0·14 | 72 |
| Mean ± standard error | | 0·44 ± 0·19 | 0·09 ± 0·03 | 211 ± 93 |
| Normal subjects (7) | Mean ± standard error | 0·35 ± 0·07 | 0·10 ± 0·02 | 96 ± 10 |
| | Range | 0·27 – 0·47 | 0·08 – 0·13 | 67 – 113 |

We have devised a method for the separation and estimation of pyruvic and α ketoglutaric acids in blood using 1 2 diamino-4 nitrobenzene which was introduced by Hockenhull and Floodgate[9] as a specific reagent for α keto acids with which it forms stable derivatives separable by paper chromatography The reagent is allowed to react with the deproteinised blood filtrate for 12–16 hours, and the derivatives are extracted with ethyl acetate and removed from the organic solvent with 5% *w/v* sodium carbonate solution After acidification of the sodium carbonate solution the derivatives are re-extracted with ethyl acetate, which is then evaporated to dryness the residue is dissolved in acetone and the derivatives are separated by paper-chromatography[10] The separated derivatives are eluted with 30% ethanol and the optical densities of the resulting solutions measured at 280 mμ

The blood pyruvate α ketoglutarate and glucose concentrations in 7 normal people and 8 ambulant diabetic outpatients are given in the table. All the patients were receiving insulin and were healthy apart from their diabetes 2 had a moderate degree of ketosis Rothera's test of their urine being moderately strongly positive at the time the blood samples were taken Inpatients or patients with intercurrent illness were excluded from the diabetic group to make it as comparable as possible with the group of normal people

The results show that there was no significant difference between the two groups in the blood levels of α keto acids. In the diabetic patients there was no correlation between the blood concentrations of glucose and of the two α keto acids

It appears therefore that in this series of patients the diabetes was not associated with any disturbance of the blood levels of pyruvic or α ketoglutaric acids over a wide range of blood glucose concentrations We propose to extend our studies to include analysis of the urine and also to investigate the blood concentrations and urinary excretion of pyruvic and α ketoglutaric acids in hospital patients with more severe diabetes

## ROYAL SOCIETY OF MEDICINE

### A Children's Psychiatric Unit in a Mental Hospital

AT a meeting of the section of psychiatry on Dec 14 with Dr W MAYER GROSS, the president, in the chair, Dr J B ROGERS described an inpatient children's psychiatric unit which has been in action at the Crichton Royal Hospital for $3^1/_2$ years

The unit (which is not the first of its kind) is, he said, contained in three houses outside the hospital grounds, each capable of taking twenty children At Ladyfield, the first house to be acquired, there are twelve boys and eight girls aged 5–14, all of normal or better intelligence Organic disorders, behaviour difficulties, psychoses, and maladjustment are represented among them They normally do ordinary school work throughout their stay, under the care of one full time and one part time teacher Some, however, when they first come, do no school work for a few days, or only 2 hours daily for a time, depending on their mental and emotional state At times a special course (called something like "domestic science") is devised for a much disturbed child, which means in effect that he has a nurse to himself for a few days The school week is varied by swimming on two afternoons in the hospital swimming-pool (and the children never enter the main hospital grounds at other times), a Wednesday visit to town to spend pocket-money, church on Sunday, and a picnic trip to country or seaside on Saturday All activities are voluntary, but Dr Rogers finds that the children are more secure if they have a regular routine even the rebellious like a framework to rebel against True discipline is based on the bargain the child makes with life "I will give up this gratification to retain your approval" To help him towards making this bargain the nurses must be secure in themselves , and they must be able to give affection steadily all the time They also need to know what stage the child has reached , and in the weekly discussions with the psychotherapist all the nurses attend and are encouraged to talk about what they have noticed The educational psychologist, the teachers, the occupational therapist, and the psychiatric social worker also attend Those who spend most time with the children are junior nurses, or cadets and they often make valuable contributions Ladyfield is staffed by three senior nurses (one a man), three assistant nurses, and five cadets , and all the domestic work is done by the nurses Ward-maids are apt to become the recipients of confidences and to form relationships with the children which are outside the therapeutic scheme, so it is necessary to do without them Dr Rogers gave examples of three groups of children and their treatment—those with educational difficulties, those who had been unable to cope with stresses in their surroundings, and psychotic children

One child, aged 9, had been at school for 4 years and was unable to read or write Tests showed him to be above average in intelligence but suffering from word blindness This had caused emotional disturbance with panic reactions After two terms of special teaching and individual help he was able to go to a special school, and later to an ordinary school Another boy of good intelligence, who had become stone deaf after treatment for tuberculous meningitis at the age of 7, expressed his frustration in severe temper tantrums He settled well, and was able in time to go to a deaf school

A girl of 8 the middle daughter of three, was rejected by both her parents and responded to stress by enuresis and encopresis She wandered about apart from the other children, but accepted the chance of daily interviews with Dr Rogers and finally spoke out her fear that she would never have a happy life because nobody wanted her The sister in charge of the unit then began to give her special attention and establis[illegible] rm relationship Thus encouraged, the child [illegible] little trouble in the dormitory banding first with two younger girls to tease an older one, and later with the older girl to tease one of the youngsters Each of the teased children had to be fortified by the affectionate attention of a nurse of her own The patient next made trouble in the occupational therapy class, and this too simmered down in time Such "testing out" behaviour on the part of an insecure child is common, and this child was also enjoying the experience of having her two sisters—vicariously—under her thumb She improved steadily all round

Psychotic children present a very difficult problem, but Dr Rogers finds that individual therapy can produce, if not recovery, at least a remission

One psychotic boy of 7 wandered alone and used infantile speech , yet he could tell the time at a glance and knew his tables up to 24 times He was given individual therapy by a woman doctor with whom he would spend at first only 10 minutes at a time Later he would stay for $^3/_4$ hour, and took *to climbing on her knee and showing infantile curiosity in her* breasts A visit from his parents caused him to withdraw again, and they were advised (contrary to all usual custom) not to visit for 3 months At the end of that time he had improved and made relations with other children He went home for 6 weeks' holiday and got on well, though his mother was not fully able to tolerate his infantile sexual curiosity On his return he played better with other children, and a second holiday at home was more successful He now appears to be almost a normal boy During his treatment the nurse had to be reminded not to leave him alone to play by himself it was only individual attention that kept him in touch with his surroundings

The psychiatric social worker sees the parents when they visit—usually on Saturday and Sunday—and the parents and home are brought into the therapeutic scheme from the beginning Some of the children come from institutions, and the unit makes the same approach to those responsible for them as it does to the parents

At Ladyfield West, the second house, the children are quieter than those at Ladyfield no hyperactive children are taken, and the atmosphere is more tranquil The third house, Hannahfield Hall, receives children with both mental and physical handicaps—for instance, a mentally defective and blind spastic girl, and a boy withdrawn in catatonia The psychotic boy already mentioned is in Hannahfield Hall, but now he only sleeps there, spending all his days at Ladyfield

The objects of the unit are to provide an environment in which the child gets the benefits of a good home influence (the mother and father figures being provided by the nursing staff), regular schooling, and hospital treatment In the interests of research each child has an ordinary case history folder, and also a separate research folder in which all that is known about him is summarised weekly Behaviour is also recorded on a chart, and these charts are already throwing light on the natural history of psychiatric disorders in children It is a common experience that the beginning of improvement does not necessarily mean improved behaviour

In a child of 11 encopresis was replaced, after 4 weeks' treatment, by violent aggression The mother, not too pleased said she had preferred him as he was *It turned out that her husband (whom she had always described as "ineffectual") had at times been imprisoned for assaulting her*

Dr Rogers hopes to follow up as many of his cases as possible for 20 years He is also trying to see all the maladjusted children in a rural area, and hopes to compare their development with that of normal children in the same area

In deciding whether or not it is important that such a unit should be part of a mental hospital he gives great weight to the part played by the nurses They must be secure maternal people, able to give love and devotion but in no sense "deprived parents" Teachers have a different function, and so have occupational therapists their part in the therapeutic scheme is primarily to teach The approach of a teacher necessarily didactic to some extent that of a nurse maternal Nurses from the hospital can be tried out in the unit and given plenty of attention while they are new to the unit Those who are interested and have a flair for the work want to stay He emphasised too the value of cadets These young girls, aged 16 and 17 are hand picked from local families and because they are young enough to enjoy playing games with the children they are a great asset, and do a first-class job He also believes that child psychiatry should not be divorced from adult psychiatry they are parts of a whole picture

### DISCUSSION

Dr D E **Sands** described the male and female juvenile departments in the grounds of St Ebba s Hospital These take boys and girls aged 12–17 He finds that sometimes a few young women from the adult wards can be suitably transferred to the female juvenile ward to the advantage of the girls Conversely boys of 16–17 sometimes do better in an adult ward The neurotics and psychotics among these young people mix well but they are intolerant of the psychopaths among them The more disruptive psychopathic girls, he finds, often settle better in a ward of young adults suffering from chronic psychoses here their antisocial activities receive neither stimulation nor response from their fellow patients in fact they get a chance to shine by contrast, and become quite helpful The difficulty is to know where to send them after treatment they usually have to go into care elsewhere, whereas most of the neurotic and psychotic patients are able to return home A special hospital for adult psychopaths has been projected but it would be incomplete without a similar one elsewhere for juveniles The phases in development in mental illness in the young are not clear cut but a not uncommon sequence in boys is from an anxiety provoking situation to a behaviour disorder then via an obsessional stage to schizophrenia and in girls anxiety is more often converted to hysterical neurosis and then to schizophrenia The transition from one phase to another can happen within a week This suggests he said that there can be no real separation of neurosis from psychosis and that these terms merely indicate stages in the development of mental illness Finally he regarded the establishment of units for children or for juveniles as within the normal scope of a mental hospital and a further stage in the fulfilment of the needs of the community by these hospitals

Dr **Kenneth Cameron** spoke of the variety of demands made on a unit such as that at the Crichton Royal It must provide an observation and diagnostic service intensive group and individual treatment and care for long term cases The first service is often hampered by the fact that once the diagnosis is made it is necessary to provide treatment and places are scarce If the child needs to be transferred to a suitable educational centre it is not always within the power of the unit to arrange the transfer He agreed heartily with Dr Rogers about the importance and value of the nursing care well trained psychiatric nurses he said adapt themselves well to the needs of child patients

In the ensuing discussion it was urged that schools for the maladjusted should not be used as an alternative to treatment in a unit such as that described The presence of psychotic and psychopathic children in such schools can greatly hinder the treatment of the children who should properly be there Dr **Rogers** agreed that maladjusted schools ought not to be used in this way He does not however care to apply the term psycho path to any child It is generally used of children who have been kicked around for years and are unable to form a relationship with anybody Given individual treatment they do at last respond and form relations with other people—at least he has not yet met one who failed to do so But it takes at least 5 years and perhaps there are exceptions he will know better in 20 years time It was also suggested that this kind of unit might well be attached to a children s hospital to which the psychiatrist might come. Good pædiatric nurses speakers pointed out can also adapt themselves to children with psychiatric problems Dr Rogers agreed on the importance of a close link between pædiatricians and psychiatrists doing this work but reminded the meeting that the equipment of a mental hospital is of service an electro-encephalograph for instance is there on the spot

Interrogated about adolescent problems destructive behaviour dancing pets and music he replied that as the children were young he had no adolescent problems He had no destructive behaviour either—or very little A greenhouse adjacent to the unit, used mainly to grow flowers for the delectation of the board of management had lost only 7 panes in $3^1/_2$ years and the children were much more destructive to the staff (in the sense of having rows with them) than to the place. A row he thinks is more satisfactory as therapy for aggression than the breaking up of coal or indeed of anything else for if the therapist goes on behaving like a reasonable person and liking the angry child the child gains security and the rows gradually stop Before the staff learned this the children took out the fireplaces and so on , but now that the staff know how to cope there is little destruction of property He encourages as many pets as the nurses will tolerate, but he finds cats get on best they have nine lives and need every one of them Country dancing singing games, and a percussion band provide the music as well as a local dance band leader with a piano accordion

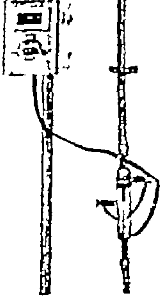
## AN ELECTRICAL DRIP RECORDER

This apparatus, made for us by Messrs Matburn Ltd consists of a drip-chamber into which are fused two electrical wires so placed that the passage of a drop of fluid makes contact with them simultaneously This completes an electrical circuit which causes a small neon bulb to glow momentarily as each drop of fluid falls from the nozzle in the chamber A small dry battery provides the power for the light which is so arranged that there is no possibility of the patient s receiving an electric shock or of a spark The whole apparatus can be earthed.



In a ward at night this apparatus will enable a nurse to be sure that a drip is behaving properly and she will therefore have no need to use a torch which might awaken a sleeping patient. In the theatre the placing of the neon light on the anæsthetist s table remote from the drip will enable him to keep a check even when the table is surrounded by onlookers

## The Spino-cerebellar Degenerations

J G GREENFIELD, M D, F R C P, honorary consulting pathologist, National Hospital for Diseases of the Nervous System London Oxford Blackwell Scientific Publications 1954 Pp 112 17*s* 6*d*

CLINICAL neurologists have for many years moved ataxically through the eponymous wasteland of the spino-cerebellar disorders But Dr Greenfield's unrivalled experience of the clinical and pathological features of these diseases, added to his extensive knowledge of the literature, has given us an informative and authoritative monograph The wise man is rarely dogmatic where information is vague and uncertain, and he recognises that no differential diagnosis is possible during life between many of the different forms of cerebellar and spino-cerebellar disease

The scaffolding to the study is built from the historical and the pathological backgrounds to the spino cerebellar disorders A short (perhaps too short) account of the anatomical and physiological considerations leads to a comprehensive classification of the degenerations, which are ranged into three main groups—predominantly spinal, spino cerebellar, and predominantly cerebellar This classification is clear and concise, and takes into account the eponyms with which the subject is burdened Instead of adhering closely to his original outline Dr Greenfield selects only a few of the types for historical and pathological discussion, and he does so in such a way that at first order appears to dissolve once more into disorder But as soon as the reader realises that this elaborative section is intended as a commentary rather than a fully organised and comprehensive statement, he can settle down to a clear and detailed exposition of the historical, clinical, and pathological features of the many forms of these degenerations, with which so many neurologists and neuropathologists have perpetuated their own names, often at the cost of confusing the minds of their successors In this survey Friedrich receives due homage, Menzel, Holmes, Déjerine, André Thomas, and others are appreciated, but Marie is consigned to whatever eternity is reserved for the uncritical The monograph ends with some comments on blindness and dementia in association with the hereditary ataxias, and there is a full bibliography

Neurologists, neurosurgeons, and neuropathologists alike, will be grateful to Dr Greenfield for removing so many of the misapprehensions caused by unselective clinical and pathological work in the past

## Tumours of Lymphoid Tissue

GEORGE LUMB, M D, reader in pathology, Westminster Medical School Edinburgh and London E & S Livingstone 1954 Pp 204 37*s* 6*d*

IN this monograph, based on 410 cases of tumour of lymphoid tissue, Dr Lumb succeeds in dispelling confusion in one of the more difficult chapters in human pathology His style is lucid, the well-chosen photographs are excellent, and the statistical tables are useful

Hodgkin's disease accounts for 46 1% of the series, as against 19 2% for lymphosarcoma and 16 9% for anaplastic sarcoma The five year survival rate for Hodgkin's disease is 34 96% (the average survival is four and a half years) as against 62 3% for follicular lymphoma and only 5 26% for anaplastic sarcoma The five year survival rate for lymphosarcoma is 22 22% over the age of thirty five but only 12 5% below that age Dr Lumb objects to the common misuse of the term "reticulosis", to him it connotes a reaction on the part of pluripotential mesenchymal cells to varying stimuli, and as such the term is analogous to fibrosis and gliosis, therefore its use in a particular sense to denote a specific disease ("one of the reticuloses"!) cannot, he says, be justified Certainly nomenclature and oncological classification can be simplified if one accepts his contention that the variation in structure of the tumours and degree of malignancy is due to the cell type *differentiation* from pluripotential cells

The book will be invaluable to the many who are concerned in the giving of prognosis As in other tumours, anaplasi [illegible] of malignancy, but there are occasional [illegible] the prognosis proves to be better than the histological appearance had suggested There are good sections on biopsy technique, including the recognition of *artefacts*, the effects of radiation, and problems in differential diagnosis There is also a bibliography and an interesting historical survey

## Leukæmia Research

*A Ciba Foundation Symposium* Editors G E W WOLSTENHOLME, O B E, M A, M B, MARGARET P CAMERON, M A, A H-L S, assisted by JOAN ETHERINGTON London J & A. Churchill. 1954 Pp. 297 30*s*

THE selection of leukæmia research for this symposium is due to the European scientific advisory committee of the Lady Tata Trust, and many of the workers invited have been supported by the trust at some time The result is a comprehensive account of current research in which all points of view are represented

Here will be found accounts of the multiplying chemotherapy, and what still remains for radiotherapy, there is a notable discussion on the virus transmission of mouse leukæmia, and at several points the question of how far these animal studies are applicable to the human disease is discussed. Fowl leukæmia studies are now less important and there is little on cell morphology Furth presented his concept of *conditioned and autonomous neoplasms*, an idea that may well be fruitful in leukæmia The account of the effect of ionising radiations has a topical interest.

This volume forms a most useful starting-point for anyone contemplating research in this field, and is a valuable summary of growing-points for those actively working in hæmatology

## The Billroth I Gastric Resection

*With particular reference to the surgery of peptic ulcer* HORACE G MOORE, JUN, M D, formerly instructor in surgery, University of Washington School of Medicine, HENRY N HARKINS, M D, PH D, F A C.S, professor of surgery, University of Washington School of Medicine Boston Little, Brown & Co London H K Lewis 1954 Pp 176 52*s* 6*d*

THIS short and beautifully produced book is a plea for the Billroth-I gastrectomy, particularly in the treatment of duodenal ulcer Chapters 5 and 8 contain the main meat in the volume The former gives the technical details for performing the operation, and the excellent drawings of the Von Haberer-Finney end-to-side anastomosis of the stomach to the duodenum are convincing evidence that the scars of duodenal ulceration are no bar to a safe gastroduodenal junction Chapter 8 weighs the evidence for and against the operation and reaches a favourable verdict There is much else to interest gastric surgeons, including some historical notes on gastrectomy in general, and a review of the literature on the dumping syndrome, in which British work receives full attention Gastric surgeons, whether they can or cannot afford to be without this book, should certainly read it

---

**Scientific Books, Libraries, and Collectors** (London The Library Association. 1954 Pp 288 24*s*)—Mr J L Thornton, the librarian of St Bartholomew's Hospital Medical College, has followed his learned history of *Medical Books*, published in 1949, with an even more ambitious volume, compiled with Mr R I J Tully of Bangor, on the history of scientific literature They bring into readable compass information which is not easily accessible, and offer a readable history of science from a new angle Instead of recording the great discoveries and advances in scientific knowledge, they plot the course taken by each scientist in making his work known In this way they guide the inquirer to the original sources for our knowledge of scientific discoveries The book covers all sciences, other than those strictly medical, from the ancient world to the end of the 19th century There are informative chapters on the growth of scientific periodical literature and of scientific societies The mathematical sciences are less fully covered than the biological, and any doctor would enjoy a great part of the book He might begin, for example, with pages 150 to 160 where the writings of the great 19th century biologists, both field naturalists and laboratory men, are admirably surveyed and implicitly related to the work of Charles Darwin

## With which we Serve

A large nation cannot live on a small island, and enjoy modern amenities, unless its people are willing to accept much more regulation of their lives and work than our forefathers would have tolerated. What we in Britain are trying to achieve is a proper balance between the claims of the community and the claims of the individual, and we hope to prove ourselves politically capable of creating order without imposing uniformity—of reaching the next millennium without passing through *1984*. Seen in this larger context, the National Health Service is an attempt to devise a system in which medical work can be publicly financed and comprehensively planned, but in which the essential liberties of patient and doctor are preserved. After six and a half years experience an unprejudiced observer would probably say that, for all its defects, this vast and complex organisation has worked on the whole surprisingly well, and the Ministry of Health's recent review of five years progress[1] is in many ways encouraging. But initial progress does not necessarily imply ultimate success, and our ingenious compromise may yet justify the pessimists—either because in the long run, it does not promote efficiency, or because it does not maintain freedom, or even because it does neither.

How the experiment turns out will depend largely on what doctors think and do about it and, as a matter of fact, different people have quite different ideas about the fundamental nature of the N.H.S., according to which of its purposes they regard as primary. With its powers of regulation and planning uppermost in their mind, many doctors, and also many laymen, see it simply as an instrument of government: having assumed responsibility for all medical care the State discharges this responsibility through a chain of command reaching from the Minister in Whitehall to the practitioner in his surgery. On this view every hospital is a branch establishment of the Ministry and every doctor is a medical officer whose principal duty is to perform the tasks allotted to him keeping most carefully to the rules. This is of course the simple readily comprehensible pattern of a State medical service, which so often strikes the layman as just what is needed and it is the pattern which we may eventually get if we make the mistake of supposing that it is here already. In point of fact, elaborate precautions were taken to prevent the N.H.S. from being a crudely authoritarian service of this kind, but if doctors themselves neither notice nor care about the difference how should the laity know better? Every time that one of us—either out of irritation or in earnest—talks of a 'State doctor' or a "State patient" he brings nearer the day when doctors and patients may be just that. On the other hand, this day need never come if the profession fixes its mind, and sets its heart, on securing what was originally intended:

> 'Though the Minister of Health took wide powers which he could hold in reserve, the Government's avowed object was to integrate, support, and supplement the work of existing medical agencies rather than to unify, regulate or supersede them. The N.H.S. should in fact be regarded not as a centralised service, in which the hospitals and doctors at the periphery exist to carry out central instructions, but rather as a confederation of medical institutions whose activities need coördination and sometimes leadership. It is these institutions, varying in size from the single-handed practice to the large hospital, that actually look after patients; and, whether as individuals or groups, they develop their own *methods and standards.*"[2]

In this concept of a confederation of institutions with its emphasis on variety and initiative, we have the antithesis of, and the alternative to, the kind of State medical service which emphasises uniformity and control.

In the closing months of his life Sir JAMES SPENCE gave much thought to the contrast between services and institutions as means of providing medical care. Unfortunately, the fragment of his last lecture which we publish this week does not contain his definition of an organised service, but he might have agreed that such a service is an undertaking in which the requirements of an authority are fulfilled by the servants of that authority. Since Parliament has decreed that medical care shall be provided and has made a Minister responsible for seeing that this is done, it has been necessary to establish an administrative service in which the Minister's servants are under a duty to carry out his instructions. To this extent the N.H.S. is in fact a centralised service under the State. But it ceases to be a service at the point where administration ceases and medical work begins, for clinicians are in no sense servants of the Minister but only of their patients. In the end what really matters is not the service—the enabling device—but the actual institutions large and small through which patients are helped, and SPENCE was deeply anxious first that these medical institutions should be good, and secondly that every doctor should think of himself always as a member of the institution where he works and never as a member of some remote service. An institution he defined as the establishment and arrangement of human effort towards a common end, carried out by the covenant of one with another"—which is something different from carrying out orders. The institution may be a general practice or a cricket club or a hospital or even something so large as a university, but there is always a risk in excessive size; because in a large institution the sense of 'covenant' or of belonging to a group is common end, is all too apt to weaken or disappear In SPENCE's opinion the big hospital, with doctors who do not know each other, is liable to lose its status as an institution and become only a sort of service, whose personnel are merely performing duties instead of being concerned together in their chosen task

[2] Memorandum of Evidence submitted [illegible] Physicians to the Guillebaud Co [illegible] 1 362

Does this philosophising lead anywhere ? Yes, if we recognise that, from the patient's standpoint, all that matters in the N H S is the excellence of its constituent institutions, and if we all—doctors and administrators alike—pay less attention to the service in the abstract and more to the means by which these institutions can be strengthened Is it not probable, for example, that the morale of some of our hospitals has been unnecessarily weakened by brigading them with others in a way that has removed their sense of identity ? In these days when we are preoccupied with establishing specialist " services "—orthopædic, obstetric, and so on—are the members of hospital staffs really given enough say in choosing their new colleagues ?[3] (Like marriages arranged by parents, appointments by outsiders are sometimes very successful, but they are by no means always the happiest start for thirty years' cooperation , and perhaps, as SPENCE believed, the post-war discouragement of institutional inbreeding has been carried to a point where it does more harm than good ) Finally, should not administrators give further thought to his remark that he knew of no example of a good hospital which has not been created through the good offices and good will of its medical staff ? The corollary to this is that damage is done when the medical staff either cannot or do not give guidance to the governing body Though the administrative decisions have to be made by the boards and committees which are part of the Minister's executive service, the doctor's responsibility and interest should be by no means confined to the care of his patient, but should extend throughout the institution of which he is a member

To organise the medical care of fifty million people on a high level, and at the same time ensure that professionally every doctor remains his own master, is an extraordinarily hard task , and we are all well aware that it may be made virtually impossible by such unfavourable factors as too little money, too much machinery, or even the rulings of judges who find no legal sanction for the doctrine of professional-responsibility—regarding the surgeon, like the boiler-man, as a servant of his board Even so, perhaps the most serious menace to the National Health Service comes from those doctors in it who feel that they have been conscripted into a service and therefore dissociate themselves from the effort to make it succeed In a small but important minority of cases this dissociation takes the active form of exploiting, or allowing their patients to exploit, an organisation towards which they feel no loyalty , but usually it manifests itself in nothing worse than a tendency to attribute all faults to " them " not to " us " When one recalls the original and deeply sincere opposition to the whole scheme, this latter degree of dissociation is indeed very far from surprising , but if (as we believe) the preservation of professional freedom in this country depends very largely on the success of the present experiment, it is a pity that any doctor should appear to want it to fail On the other side, however we must remember that, in medicine as elsewhere, continual criticism is a necessity , and also of course that the English are apt to speak disrespectfully of what they hold most dear—unless, indeed, someone else does so What any doctor says about the service does not, after all, matter nearly so much as what he does about the particular medical institution where he works Granted their present faults, it is these institutions that give us so much cause for both pride and confidence

## Anticoagulants for Myocardial Infarction

WE make no apology for returning to the topical subject of the management of the effects of coronary occlusion or insufficiency Since we last commented on this matter,[1] the Committee on Anticoagulants of the American Heart Association has published a study of 1031 cases The authors of this important account—IRVING S WRIGHT, CHARLES D MARPLE, and DOROTHY FAHS BECK[2]—justify its exhaustiveness by pointing out that every year about 200,000 persons in the U.S A die from myocardial infarction and 600,000–800,000 suffer attacks " Perhaps the greatest personal and social significance of myocardial infarction lies," they say, " in the large number of persons lost by death during their most productive years—years when their talents are most needed by their families, their professional or industrial groups and their nation " The figures of age-distribution emphasise this 16% of the patients in their series were aged 40–49, and 35 9% were aged 50–59 , and the patients were mostly males—87 3% of the first of these age-groups and 84 6% of the second The 1031 patients were divided into 589 who received anticoagulant treatment and 442 who did not and who served as controls Sixteen hospitals cooperated in the survey and used uniform methods of case taking and treatment The analysis of the symptoms shows that the well-recognised clinical picture is a correct one pain, fall in blood-pressure, pyrexia (100°F or more), increased erythrocyte sedimentation rate, increased pulse rate, and a white cell count of 9500 or more per c mm are the commonest findings, cardiac enlargement or failure and abnormal rhythms are less prominent

It is very clear that the danger of myocardial infarction, once the patient has survived the first twenty-four hours, lies in thrombo embolic complications , and it is also clear that the effectiveness of anticoagulant treatment lies in its ability to prevent these complications The American team conclude that anticoagulants substantially reduce all types of complication whether intracardiac or extracardiac including emboli originating in mural thrombi From the high rate of thrombo embolism in the first week of the illness and from the observed effects of delay in treatment, they recommend that anticoagulant treatment should be begun as soon as possible and the prothrombin level lowered as rapidly as possible The anticoagulant treatment should last for at least four weeks after the initial attack, and should thrombo embolism occur, the treatment should be continued for four weeks from the last such incident The team are in favour of long term anticoagulant treatment for patients with a record of repeated myocardial infarction. Protection is greatest when the prothrombin times are kept at between two and two and a half times the normal level (about 23% prothrombin or less) The association of anticoagulant therapy with reduction in the risk of thrombo-embolism though noted at all ages was greatest in the 50–60 age group but anticoagulants did not remove the upward trend of complications with increasing age The data suggested that without anticoagulant treatment the risk of thrombo embolism is greater in men than in women, but anticoagulant treatment reduces the incidence greatly in both sexes and rather more in men than women Consequently the team suggest that anticoagulant treatment is suitable for all patients regardless of age or sex The data support the view that anticoagulants are effective in both mild and severe cases both types will benefit from maximum protection from the onset The authors conclude that their results do not support the contention of RUSSEK and ZOHMAN[3] that 'good risk' cases—i e those with no unfavourable signs at their first examination—do not need anticoagulant treatment WRIGHT and his co workers are quite clear that good risk cases showed fewer thrombo-embolic complications when given anticoagulants, and they point out that the screening for good risk cases involves a great possibility of error

---

[3] *Lancet* 1948 ii 101

[1] *Lancet* 1953 ii 171

[2] Myocardial Infarction Its Clinical Manifestations and Treatment with Anticoagulants By I S WRIGHT, C D MARPLE, and D F BECK New York Grune & Stratton. 1954 Pp 656 $8 50 See also *Lancet*, 1954, i 92

Provided that the prothrombin time is kept at two to two and a half times normal, the danger of hæmorrhagic complications is small lowering still further the prothrombin level increases the risk of hæmorrhage and gives no added protection against thrombo embolism To maintain a smooth level of prothrombin reliable laboratory control is essential and the committee are not in favour of giving anticoagulants without such control The hæmorrhagic complications during anticoagulant treatment have been exhaustively analysed Some evidence of bleeding was observed in 12 0% of the treated patients, but it was also found in 5 2% of the control group and in only 7 8% of the treated group was the bleeding ascribed to the anticoagulant No less than 54% of these bleeding episodes were mild (mostly microscopic hæmaturia), 30% were classified as moderate there were in fact only 4 severe bleeding episodes among the 577 treated patients considered and in only 1 was the anticoagulant clearly the sole factor causing the bleeding None of the clinically observed cases of hæmorrhage was fatal but some unsuspected hæmorrhages were discovered at necropsy in fatal cases. Nevertheless the team believe that the benefits of anticoagulant treatment greatly outweigh the risk of hæmorrhage Patients with complicating azotæmia or with renal diseases and to a lesser extent patients with liver enlargement or myocardial failure have a greater tendency to bleed but the added risk is not great enough for anticoagulants to be withheld

The data show clearly that administration of anticoagulants reduces the risk of death, during the period of observation only two thirds as many patients per 100 died in the treated group as in the control group (TUDHOPE and DONALD[4] have already described evidence suggesting that in survivors one month after myocardial infarction the mortality rate during the subsequent eleven months is considerably lower among those who have received anticoagulants than among those who have not) The reduction in deaths in the American series appears to be due primarily to the prevention of thrombo-embolic complications, since in 42% of the control group (compared with 23% of the treated group) death was preceded by clinically diagnosed thrombo embolic complications Furthermore the contrast in death rates between the control and the treated groups was greatest in the second, third, and fourth weeks when anticoagulant treatment was most effectively maintained The necropsy findings on patients who died showed that nearly three quarters of the original infarctions were due to thrombi and were "potentially preventable with anticoagulant treatment, provided the need could have been anticipated and therapy instituted in time" Coronary insufficiency accounted for 15% of the cases, and 11% were attributed to miscellaneous or unknown causes Only 3 4% of the original infarctions were due to subintimal hæmorrhages Calculations showed that rupture of the heart or intracardiac hæmorrhage was an immediate or contributing cause of death in 2 4% of the control patients and in 4 1% of patients who had received anticoagulants but in contrast the death rate from thrombo-embolic complication was reduced fivefold in the treated group All the same, the American team reasonably point out that the risk of intracardiac hæmorrhage should be reckoned with and watched for by clinicians treating patients with anticoagulants and that by good management of the anticoagulant control this risk can be minimised

It needs no great perspicacity to deduce from all this that the authors of the report are wholeheartedly in favour of anticoagulant treatment for *all* patients with myocardial infarction whether mild or severe They consider that treatment should be begun as soon as possible, using heparin if necessary for the first twenty four to forty-eight hours and be continued for four weeks 'provided no significant contra indications are present and the facilities are available for meticulous supervision of its administration.' These conclusions are the same as those reached by GILCHRIST and TULLOCH[5] from a study of 321 cases seen in Edinburgh over a seven year period The committee's report is concerned only with patients treated with dicoumarol or ethyl biscoumacetate but the use of newer anticoagulants[6] will not change their conclusions since these drugs make control more effective Opposing the conclusions of IRVING WRIGHT and his school RUSSEK and ZOHMAN[7] have reiterated their view that, by assessing eight important signs and symptoms it is possible to classify patients into good and poor risks and only the poor risk cases need anticoagulant treatment Of 1318 patients admitted to hospital with myocardial infarction 46% were classified on the day of admission as good risk cases and RUSSEK and ZOHMAN contend that for this large proportion of patients the mortality and incidence of thrombo embolism is so low that anticoagulant treatment, with its added risk of hæmorrhage, cannot be expected to improve the prognosis They also point out that most of the deaths in the good risk group occur in the first forty-eight hours, when anticoagulant treatment does not give protection, and thrombo-embolism after the first forty-eight hours is relatively infrequent So RUSSEK and ZOHMAN estimate that only 30% of all patients with myocardial infarction require anticoagulant therapy It is clear, from a series of questions and answers published by SCHNUR,[8] that American opinion is far from unanimous on this question The majority are taking a middle course HALPERN et al ,[9] for instance, administer anticoagulants in all cases for the first forty-eight hours, thereafter discontinuing this treatment where the prognosis is judged good. Others reach an immediate decision, withholding anticoagulants from patients with mild first attacks But the answers to SCHNUR's questions show that, since the public knows of these drugs, it is often difficult to withstand the relatives' demand for their use

## Pulmonary Embolism

PULMONARY embolism, it is now realised, is much commoner than was formerly supposed In the aged and enfeebled its supervention may be stealthy and easily overlooked , indeed, it may deserve the title of the acute disease most likely to escape detection Sudden death from massive embolism after operation is familiar enough , and the case of the patient with obvious heart-disease or phlebothrombosis in the leg who begins to have pain in the chest, hæmoptysis, a pleural rub, and an abnormal shadow on the chest radiograph is rarely misdiagnosed But often the clinical picture of pulmonary embolism is far less typical Moreover, although good radiographs will nearly always reveal some abnormality,[10] radiographs of elderly obese invalids taken with a bedside apparatus are often not very helpful , and it is among such people that pulmonary infarction is most usual Necropsy figures such as those published by MORAN [11] and TOWBIN [12] leave no doubt about the frequency of this complication TOWBIN, for example, in 512 necropsies on the late inmates (mostly elderly folk) of a social-welfare institution at Columbus, Ohio, found emboli in the lungs of 25%, and of 34% where death had occurred after the age of 70 TOWBIN does not state exactly how many of these emboli had been diagnosed during life, but he makes it clear that many had been either overlooked altogether or mistaken for coronary thrombosis or bronchopneumonia TOWBIN has been at pains to compare the pattern of illness and death in his institution with that in the surrounding city , and he concludes that a similar incidence of pulmonary embolism is to be expected during terminal illness in older members of the general population Of course not every embolus discovered at necropsy has necessarily been the cause of death , in some the embolism may simply have been the coup-de grâce in a chronic illness Nevertheless a disorder that is so common , so dangerous is a serious challenge, which is likely to grow in importance as the population ages and other immediate causes of death, such as infection, are gradually eliminated.

The problem of pulmonary embolism is threefold how to prevent it, how to recognise it, and how to treat it In the absence of heart disease nearly all emboli come from clots in the deep veins of the legs [13] Not all the causes of such venous thrombosis are clear , but there is little doubt that in elderly people one important cause is enforced rest in bed, especially when this has been brought about by an infection, for some infections are known to be accompanied by an increased tendency to clotting of the blood Old folk tend to go to bed for comparatively slight illness, and in this they are often encouraged by well-meaning relatives They should, on the contrary, be prompted to remain ambulant as long as possible Postoperative phlebothrombosis is not easily prevented , early ambulation has not reduced its incidence LAMBERT ROGERS [14] believes that pressure by the operating-table on the calves of the legs can obliterate the intermuscular veins and predispose to clotting, and conceivably this may also be true of the frequently flinty hospital bed-mattress Pulmonary embolism from an unsuspected thrombus is particularly liable to occur when the patient first gets out of bed, and SHORT [15] has therefore suggested that anticoagulants should be given routinely during this danger period

The recognition of pulmonary infarction depends on constant vigilance Any older person confined to bed who suddenly begins to have unexplained pyrexia, dyspnœa, or chest pain should be suspected of having embolism and should be carefully examined for evidence of preceding phlebothrombosis Infarction is often particularly quiet when masked by existing heart-failure , but sometimes its onset is betrayed by unexpected tachycardia or cardiac arrhythmia [15] Once deep-vein thrombosis, with or without embolism, has been diagnosed, anticoagulants should be given unless there are strong contraindications With careful treatment the mortality risk is probably no greater than 2% or 3%, even among older patients The death-rate from pulmonary embolism after untreated femoral-vein thrombosis is of the order of 10% Unfortunately fatal pulmonary embolism is often unheralded [16] , but if embolism has already occurred, anticoagulants will reduce the likelihood of further embolism Intravenous trypsin has been used experimentally to dissolve intravascular thrombi, but it has not yet been proved to deserve a place in clinical practice[17] When there has been repeated embolism despite adequate anticoagulant treatment, it may sometimes be necessary to tie a vein , but ligation of large vessels, such as the inferior vena cava, is not to be lightly undertaken, for the late sequelæ are often disabling [18]

## ACTION ON AGENE

THE Minister of Food's announcement, reported on p 53 of this issue, that manufacture of agenised bread is to cease at the end of 1955 is the tardy outcome of a disturbing discovery in 1946 In that year Mellanby[1] ound that agenised flour in large amounts induced "hysteria" in dogs; and it was shown to cause a similar disturbance in some animals other than dogs Rapid progress was made towards the identification of the toxic substance.[2] Meanwhile a committee set up to examine the suitability of this flour for human consumption reported in January, 1950 that though it had not been proved to be toxic to man its use should be discontinued[3] This recommendation the Government of the day accepted But in the intervening five years no action has been taken; and in answers to parliamentary questions the failure to act has been variously ascribed to the inevitable delay in conversion of flour mills to the need for finding a suitable alternative flour improver and to deferment of a decision pending the receipt of a report of an investigation under the ægis of the Medical Research Council This report to which the Minister of Food referred in his statement confirms that agene treated flour induces fits in dogs. The M.R C investigators examined four other means of flour improvement—chlorine dioxide, potassium bromate, ascorbic acid, and an aeration process—and though these methods were found to have different effects on flour, the evidence was insufficient to call for the abandonment of any of them These methods are to be kept under close scrutiny Presumably millers will use one of the four in place of agene

The facts included in the Minister's statement make us little wiser than we were at the start of 1950 But we can be thankful that the sensible action of banishing the agene process is at last to be taken

## METHYL MERCURY POISONING

THE danger of methyl mercury compounds has been known for nearly a hundred years[4] Such compounds are manufactured in large amounts for the control of agricultural fungus diseases and in 1940 Hunter Bomford and Russell[5] described four cases of poisoning in men engaged in this manufacture. Now fifteen years later one of the four has died and the irrecoverable damage caused by these substances has been described[6]

The destruction proved remarkable for its sharpness and selectivity Circumscribed areas of the visual cortex on the medial surface of the occipital lobes were atrophic and scattered small foci were present elsewhere in the cortex similar sharply defined areas in the depths of some cerebellar folia had lost their granular layer of neurones and secondary changes were present in the glia the Purkinje cells and the superficial layer of fibres the cord and peripheral nerves were not affected These changes account for the clinical signs of great general ataxia and extreme concentric reduction of the visual fields The lesions differ conspicuously from those in the relatively acute stages in the rat and the monkey; here degenerative changes involved the spinal cord and peripheral nerves If this is also the pattern in man it is apparently reversible and the clinical picture indeed suggests that temporary involvement of the nervous system far exceeds the permanent damage

This is the first demonstration in man of primary cerebellar degeneration due to an exogenous toxin and methyl mercury compounds are an important addition to the list of toxic substances with a precise localised effect on the brain The extremely sharp localisation to the depths of particular cerebellar sulci is striking such selectivity is a question sometimes of access sometimes of physiological over use sometimes of a higher organisation and more complex and delicate structure of the cell and its function but none of these explanations seems to apply here, and some chemical difference must be assumed in the affected cells of what to the relatively crude eye of the microscope seems a singularly uniform organ

## FIBRO ADENOSIS AND BREAST CANCER

THE question whether cancer of the breast develops more commonly in patients with fibro adenosis than in other women has never been satisfactorily answered With the intention of settling it Dr William Kiaer[1] has examined 700 breasts from necropsy specimens obtained from women who, during life made no complaint of their breasts and in 33% of this series found histological evidence of fibro adenosis In the 700 breasts examined only 1 case of carcinoma was discovered and he concludes that unlike carcinoma of the prostate latent carcinoma of the breast must be very rare From a study of this material he divided fibro adenosis into three grades, according to the severity of the histological picture Next he made a histological study of 378 breasts in which there was a cancer and 58% of these were found to have fibro adenosis elsewhere The association was particularly distinct with the intraduct type of cancer furthermore it was the grade III (or severest) type of fibro adenosis that was found most often in these cases, and in many a morphological transition from grade III fibro-adenosis to breast cancer was observed microscopically The fibro-adenotic changes were found to be more pronounced in the region of the breast adjacent to the cancer

A further 334 cases of fibro adenosis were examined from the clinical point of view The age distribution showed a peak between 35 and 49 years and the *left* breast was found to be affected more commonly than the *right* *The menopause occurred earlier in this series* than in the normal Where histological control was available it was found that when the patient complained of a discharge from the nipple this was associated with a more severe grade of fibro-adenosis There was no relation between pain in the breast and the grade of fibro adenosis—pain being Dr Kiaer believes, an expression of the fibrosis Of these 334 patients 321 were followed up to see whether cancer developed more commonly in them than in the general population Dr Kiaer refers to Bloodgood's change of heart on this matter which he regards as typical when Bloodgood was a histologist he thought that fibro adenosis frequently led to cancer but when he became a clinician he realised that this relation was far less obvious than histological evidence would suggest Of the 321 patients who were followed up 17 were watched for less than five years 41 for between five and ten years and 203 for more than ten years 21 (6 5%) developed carcinoma of the breast during the period of follow up Histological evidence showed that the higher grades of fibro adenosis particularly grade III were especially likely to lead to cancer and furthermore excision of the grossly affected area did not confer protection Dr Kiaer is aware of the objection that his grade-III fibro-adenosis may be a form of cancer; but he thinks that this is very unlikely because the latent period between the complaint of the symptoms of fibro-adenosis and the appearance of the

cancer was generally so long and because many of his cases of grade III fibro adenosis never developed a metastasising lesion

The whole series is analysed statistically by Arne Nielsen, an actuary from the Danish cancer registry, who concludes that breast cancer is 4–5 times as common in patients with fibro adenosis as in the normal population Whether or not this estimate is correct, it seems clear that there is some increased tendency for cancer to develop in patients with fibro adenosis

## RECOGNITION OF TABLETS

We recently *referred to the difficulty of identifying* medicinal tablets [1] This may sometimes be a vital matter, as when an almost empty tablet-box is found beside an unconscious patient Cooper [2] has devised a series of simple chemical screening tests by which many common drugs can be quickly recognised Six reagent solutions are required A few milligrammes of the tablet material is powdered and placed in small heaps on filter-paper A drop of test solution is added to each heap of drug and any colour change is noted By reference to a chart the drug can usually be identified or allocated to a small group If the solutions are already prepared the test takes ten minutes This is an important step forward But it might be objected that the tests, although they have been "streamlined," require time, care, and some apparatus, that the reagents do not keep long and at least some of them may have to be prepared fresh for each test, and that the procedure is inadequate for identifying compound tablets Ideally the responsibility for ensuring that tablets are readily identifiable should rest with the maker Perhaps manufacturers should consider stamping each tablet with an agreed code-number

## TUBERCULOUS PLEURAL EFFUSIONS

Tuberculous pleurisy may seem at the time a short-lived, though uncomfortable, illness But in many patients manifest pulmonary tuberculosis develops later Estimates of the proportion vary,[3] but apparently 20–30% will require further treatment in the next five years The pleural effusion is commonly a gross manifestation of small lung lesions These may not be apparent in the ordinary chest radiographs, but tomography is said to reveal them in about 12% of cases [4] The future of the patient depends on the behaviour of these lesions rather than of the pleura

Long rest and protracted convalescence are usually recommended, but there seems some doubt whether this reduces materially the risk of breakdown Mitchell [5] studied 186 patients treated with varying periods of rest in bed The rate of breakdown in the first five years was 22% among those rested in bed for less than three months and 19% in those rested for longer than six months Emerson [3] found that in 22% of a group of young adults who had had pleural effusions further manifestations of tuberculosis developed in the first two years, even though they had had three months' complete rest in bed He points out that the mean morbidity-rate in the many previously reported series is 30% for those treated with long continued rest and 29 9% for those treated without this

Mackay-Dick and Rothnie [4] advocate repeated aspiration of the effusion and breathing exercises, in order to reduce the risk of later respiratory impairment They claim that the effusion disappears more quickly, but their evidence is not entirely convincing Even if this claim is correct, there is no evidence that the duration of the effusion influences the degree of respiratory disability In any event, it is rare to find any serious disability at all, and the pleura seems to have an astonishing ability to heal It is undoubtedly more important to try and prevent pulmonary relapse, and Mackay Dick recommends treating all patients for six months with antibacterial drugs There is much to be said for protracted drug treatment, and possibly six months is not enough There are, however, arguments against even six months' treatment Some might maintain that it is better to keep the patient under close observation and administer drugs promptly to the 30% who relapse, thereby sparing the remaining 70% the disadvantages of protracted drug therapy It is theoretically possible that the bacilli may become resistant to the drugs during the initial course, and treatment of subsequent relapses will accordingly be less effective, thus although few patients may relapse the same number may die of the disease or have long illnesses Indeed, it is not even known whether antibacterial treatment reduces relapses This would not have been difficult to establish by a controlled trial in the early days of drug treatment, but such a trial would now be difficult and might be unjustifiable Most physicians will probably prefer to judge each case individually

## RABIES IN GERMANY

An epizootic of rabies, described as more serious than any in Western Europe for at least a century, has been spreading westwards across Germany and now threatens neighbouring countries It was discussed at a recent meeting of the Public Health Committee of the Brussels Treaty Organisation [1]

After the first world war, infected dogs, wolves, and foxes from the east caused an outbreak on the eastern borders of Germany This reached a peak in 1924, but veterinary police measures thereafter kept infection beyond the frontiers until the second world war, when it again increased The disease seems to have been prevalent in Eastern Germany from 1945, particularly in foxes and wolves, which could not be shot because the people lacked firearms By 1948 the epizootic had passed the Schleswig Holstein border in the north and reached Austria in the south, and had passed from foxes to dogs, though it preserved its essential difference from earlier outbreaks—namely, the infection of wild rather than domestic animals [2] In 1951 Eastern Bavaria was infected and by last spring large areas from the Danish frontier to Hesse, and some districts bordering the Dutch and Belgian frontiers, were declared infected or suspected Thus in about ten years the epizootic has spread stealthily right across Germany, though most of *the southern parts of Western Germany remain free*

Though the disease is more easily detected in domestic than wild animals, two thirds of the material diagnosed as rabies in the government veterinary laboratories have *come from wild animals* (foxes, badgers, roe deer, hares, rabbits, weasels, wild boars squirrels, rats, buzzards, and magpies) cats, dogs, cattle, and other domestic animals have provided the remainder, though in herbivores infection is rare Incidence is highest in winter and spring, and rivers seem to be no obstacle to spread The chief diagnostic signs are the well known changes in behaviour Thus foxes lose their fear of man and may be seen walking in a village street they have even allowed themselves to be picked up by children Refusal of food, and biting of inanimate objects are characteristic as are changes in voice Buzzards, in which Negri bodies were afterwards found, have dashed themselves to death against windows In material from animals in which rabies has been clinically confirmed, Negri bodies have been found in about 75% [3] In addition, the intracerebral and intramuscular injection of suspect material into white mice is employed

[1] Netherlands report to the Public Health Committee of the Brussels Treaty Organisation Unpublished
[2] Zunker M *Bull Off int Epiz* 1954, 42, 83
[3] Ruppert F *Ibid*, p 70

Only one case of human rabies has occurred in Western Germany, but the number of people vaccinated is large and rapidly increasing—i e 423 in 1953 and 828 up to June 5 1954 the greater part from Lower Saxony North Rhine Westphalia and Hesse Vaccination is recommended for all who have been bitten scratched, or licked by infected or suspected animals who have handled them, or who have been in contact with their saliva (e g on muzzles or pieces of wood) No cases of postvaccinal paralysis are reported and hyperimmune serum has not been employed

The basic control measures are first notification secondly destruction of foxes and badgers by shooting and cyanide fumigation of the earths and thirdly declaration of infected or suspected areas. In such areas dogs must be kept tied up for three months and cats kept at home any found at large are shot and since sooner or later a cat will walk by itself,' most cats in these areas have been killed Energetic measures against foxes—3000 have been destroyed in the province of Detmold (North Rhine Westphalia) in eight months—seem to have been effective in stopping the epizootic Education of the public is regarded as very important [4] It is noteworthy that vaccination of dogs has been rejected as a control measure on the grounds that (a) wild animals are chiefly affected (b) cats are considered more dangerous than dogs ; (c) police measures have been successful in the past in controlling infection in dogs (d) vaccinated dogs must still be controlled because their saliva is infectious even though they are protected against clinical development of the disease ; (e) the public would be less likely to coöperate in other control measures if dogs were vaccinated and (f) the cost and effort in vaccinating all dogs would be very great For these reasons the vaccination campaigns such as have been successful in Hungary Japan Israel and Malaya [5] are not thought to be applicable to conditions in Western Germany

Denmark has so far remained entirely free, thanks perhaps to destruction of foxes along the frontier and mass vaccination of dogs in frontier areas It seems unlikely however that such measures will stop the epizootic from crossing the long western frontier of Germany

For us the moral is clear Quarantine has fallen into disuse as a prophylactic measure against many diseases, but against animal rabies it remains our great protection Anyone smuggling in a dog from Western Germany commits not only an offence but a serious crime against the canine—and perhaps the human—population in this country

## ANTIGENICITY OF COLLAGEN

AMONG connective tissue diseases rheumatic fever has always seemed to have the best claim to an immunological origin Yet although the evidence implicating the group A hæmolytic streptococcus is strong no particular bacterial antigen or antibody has been identified as a specific causal factor Alternatively the antigen may lie in or be derived from the connective tissue itself and auto antibodies may be the cause of lesions involving among other possible components collagen Hitherto collagen (which is by bulk the chief component of connective tissue) has been thought to be non antigenic as is its soluble derivative gelatin and its immunological harmlessness is presumed in its use (in a somewhat modified form) as surgical catgut Reticulin however which in some ways resembles collagen probably has immunological activity the work of Hill and Cruickshank [6] on fluorescein labelled tissue antibody strongly suggests that the antigenic component in kidney glomeruli, for example, is reticulin

Evidence is now forthcoming that soluble collagen is also antigenic Watson et al [7] have prepared acetic acid extracts of rat tail tendon with special care to prevent denaturation and have immunised rabbits by intraperitoneal infusion of the extracts After somewhat prolonged immunisation some of the rabbits produced antibody giving specific complement-fixation results with the immunising solution Their experiments are designed to meet the criticism that the antibody produced is not specifically directed towards collagen but to an accompanying impurity and their results justify their conclusion that they have obtained an antiserum specific for the acetic acid soluble component of collagen Particularly striking is their demonstration that whereas the addition of normal rabbit-serum to the acid-collagen solution led to the reconstitution of fibres which sometimes showed the characteristic collagen periodicity in electron micrographs the addition of the specific rabbit-antiserum gave rise instead to a globular form of precipitate which never included fibres with periodic banding They also describe evidence (and this if confirmed is another important new finding) that collagen exhibits species specificity

These results clearly hold promise of an effective method of investigating connective-tissue reactions to specific antibody

## PRIVATE ADVENTURE MONEY

SINCE it was founded in 1943 the Nuffield Foundation has allocated grants of over £5 million and with its annual report for 1953–54 [8] it publishes a full survey [9] of all the grants made during its first ten years These reports appear at a moment when the great American foundations face Congressional criticism. Like their creators the Carnegie Rockefeller and Ford Foundations are big enough to speak for themselves but their generosity has been international and British scientists can gratefully apply to them all the words Dean Rusk has written about the Rockefeller Foundation

> As a social institution it reflects the application to philanthropy of the principles of private initiative and free enterprise, under public policies which have long recognized the benefits of such activity to a free society [10]

Though research education and welfare services in this country receive more and more help from the State there is still plenty of room here for imaginative experiment But in some of the other countries of the Commonwealth the gaps are even more conspicuous and in the past few years the Nuffield Foundation has accordingly given more private adventure money " to people and institutions in overseas parts of the Commonwealth One of the most important of these allocations has been grants of £250 000 to university colleges in Colonial territories This generous help will give the foundation a particular pleasure which we all share, in the announcement last month that the University of London has confirmed the conferment of M B B.S degrees on thirteen students of the University College of the West Indies who passed their final examinations in October

As one quinquennium ends the next begins and the report also outlines the foundation s plans for the next five years. As its special interest in medicine it has chosen the investigation of the chronic rheumatic diseases and the causes of mental and physical defects which throw so heavy a burden on the family and the community ' It also shares Professor Adrian s belief in the importance of the development of the social sciences, and it hopes to encourage fundamental research into such subjects as the family For instance, Belmont Hospital, Surrey, over three years, is to receive up to £19,500 for a study of the family and social background of some patients in the unit lately described in our columns by Dr Maxwell Jones[11] The foundation's interest in the problems of old people is of long standing, and here it hopes especially to help in research and practical experiment in the employment of elderly workers

## ULTRASONIC IRRADIATION OF THE FRONTAL LOBES

THE effects of ultrasonic waves on biological systems have interested experimentalists for nearly thirty years In the past ten years they have been used to damage various parts of the brain in living animals Lynn and Putnam[12] found that neurones were more severely affected than glial cells, and that blood-vessels suffered least In their experiments the scalp and skull were not opened, and radiation intense enough to harm the brain caused also dry gangrene of the superficial tissues The mode of production of lesions is obscure The absorption of ultrasonic energy by homogeneous liquids is not fully understood, and conditions in the brain must be even more complex

In what appears to be the first report of the use of ultrasonic energy in neurosurgical practice, Lindstrom[13] describes its effect in twenty cases in which the prefrontal lobes were irradiated—in seventeen cases of malignant disease for relief of intractable pain, and in three cases of organic nervous disease with psychiatric complications Preliminary trials in rabbits showed that the cerebral effects were uselessly variable unless the scalp and skull were opened

In dogs and rabbits it seemed to matter little whether the dura also was reflected The transmitting quartz crystal, 1¹/₄ inches in diameter, oscillated at 1000 kc per second The waves were conducted to the brain through Ringer's solution percolating through a plastic cup, either cylindrical, or conical to focus the beam Maximum energy was estimated to be 7 watts per cm² cross section area of beam near the crystal. The aluminium face of the oil filled crystal container was separated from the brain by 1 5–4 0 cm of Ringer s solution In the animal brains lesions were found mainly in the white matter, following especially the contours of its junction with the over lying grey, which was often apparently unharmed

In patients 1¹/₄–1¹/₂ inch buttons of bone were removed from the frontal bone, 1 cm in front of the coronal suture and in line with each pupil The beam was aimed in the direction of the tip of the anterior horn of the ventricle on each side Exposure time was four to seven minutes with dura open seven to fourteen minutes with dura intact Fourteen of the brains were later obtained for anatomical study, when the lesions were between nineteen days and seven months old Detailed descriptions are promised later

Macroscopically, most brains appeared normal Microscopically the inconspicuous cortical damage was consistent with the use of diathermic coagulation for dural bleeding Scattered small foci of gliosis were found in the white matter, especially near its junction with the cortex, near blood vessels, and near the tip of the ventricle Yet, notwithstanding the relatively slight structural changes, ten of the seventeen patients with painful malignant disease were completely relieved, and four more were partly relieved, of their complaints

The indications for destructive operations on the frontal lobes will continue to be debated All parties to the debate will need to take this new method into account It is not too much to ask that no neurosurgeon should use it on his patients without having standardised the performance of his apparatus experimentally The ultrasonic method does seem to offer new possibilities of inflicting damage which, presumably maximal at first, may be partly reversible, so that the permanent damage is very much less than that caused by s lobotomy If further clinical and pathological experience confirms the results in this small series, will it not suggest the possibility that temporary lesions may break up, for example, some habitual mental attitude, and that this need not return when neuronal structure and function are later partly restored ?

## LYMPHŒDEMA PRÆCOX

THE lymphatic circulation, carried as it is in fine transparent vessels, has been largely neglected by clinical investigators, other than those interested in cancer dissemination This is due partly to the difficulty of displaying lymph-vessels and partly to the lack of an adequate clinical method for determining their functional efficiency Kinmonth[1] has reviewed some of the methods at present in use

Patent-blue V is a convenient dye for the study of lymphatic pathways, and can safely be injected into the subcutaneous or deeper tissues "Streamers" of dye-filled lymphatics can be seen to leave the injection site, and massage or limb movement forces the dye into the regional lymph nodes The blue tinge following superficial injection disappears in forty-eight hours Kinmonth has shown that dye injected into the interdigital spaces of the normal foot or hand is quickly demonstrable in the groin or axilla, and similarly it will outline the lymphatics in the spermatic cord, breast, or mesentery. Sometimes a lymphatic revealed by patent blue V has been successfully dissected out and injected with a radio-opaque material, such as diodone

In the normal limb the diameter of the lymphatic trunks, which anastomose and bifurcate as they approach the root of the limb, remains relatively uniform But in lymphœdema præcox[2] the lymphatics in half the patients are tortuous, dilated, and incompetent They are valveless and may be reasonably compared to varicose veins, and dye techniques have revealed incompetence of the deep lymphatics in addition to the well recognised superficial lymphatic abnormality Jepson et al.[3] attempted to assess the removal rate of tissue-fluid and thereby lymphatic efficiency, by estimating the absorption of radioactive protein, and Kinmonth[1] has applied this technique to lymphœdematous limbs, and suggests that in these dispersion of the tagged protein is slower than normal Analysis of tissue fluid in lymphœdema reveals high levels of protein, except in cases of chylous reflux when the œdema fluid has a high fat content

These findings in the lymphœdematous limb should be kept in mind when the question of operation arises. An operation designed to repair the anatomical and functional defect seems to be out of the question, since both deep and superficial lymphatics are at fault, the introduction of valved lymphatics by a skin bridge from the abdomen to the thigh only nibbles at the problem. Apparently the surgeon must rely on excisional surgery by which the œdematous subcutaneous tissue is radically excised and the leg shaped for cosmetic effect Development in skin grafting methods—for example, the use of the electric dermatome—have greatly simplified skin replacement But such major operations, which are often associated with considerable blood loss, must be kept for the occasional case where the leg is so huge that it handicaps the patient mechanically

## OBSTETRICS AND PSYCHIATRY *

G R HARGREAVES
O.B.E , M.R C.S
CHIEF OF THE MENTAL HEALTH SECTION WORLD HEALTH ORGANISATION

OBSTETRICS has the unique distinction of being the only branch of clinical medicine which concerns itself predominantly with healthy human beings, and occupies itself principally with assisting a physiological process rather than with interrupting one which is pathological Psychiatrists, on the other hand, are generally assumed to devote their interest to patients whose symptoms make them appear so remote from their fellow human beings that they are thought of as *aliénés*; a psychiatrist, at any rate in the eyes of those who call him an alienist appears to occupy himself with 'foreigners, which means, as every Englishman knows, people who are far from normal

When I say that nevertheless obstetrics and psychiatry share an important area of common interest I am not referring merely to the puerperal psychoses. The puerperal psychoses are to the psychiatrist important chiefly as the presenting symptom of a much larger group of psychological problems associated with childbirth which like the main bulk of an iceberg are not so easily visible (Indeed psychiatrists would suggest that the only thing common to the psychoses of the puerperium is the fact that they occur during the period after childbirth for they include almost every type of psychosis which may occur at any time of life ) The psychoses arising in childbirth or any other situation are outnumbered, at any rate in the Western countries by the psychoneuroses

The fact that this is still little recognised by physicians who are not psychiatrists arises partly from the deficiency in this respect of most current medical education but also from the fact that the manifestations of a neurosis are little evident to the observer and may easily be ignored by everyone except of course the patient whereas the destruction of the personality which accompanies a psychotic illness leads to disturbances of behaviour which even the most obtuse observer will perceive

But whether a patient be suffering from the comparatively rare condition of psychosis or the far more common one of psychoneurosis the psychiatrist as he takes his history cannot fail to be impressed by the frequency with which he finds the occurrence of pregnancy and birth as one of the ætiological threads in the weaving of the illness whether it be the pregnancy of the patient herself or the pregnancy or birth of others intimately involved in the patient s life situation

### STRESS

Whereas it was formerly supposed that mental illness was hereditary we would now prefer to say that what is inherited is not the illness but the possibility of developing it Whether a person who inherits this possibility does in fact develop the disorder depends on the emotional stresses of his life experience and his reaction to these stresses depends partly on the experiences themselves and perhaps partly also on another hereditary factor of general resistance—of capacity to adapt constructively to such emotional stresses

Emotional stress, in the sense of the psychiatrist, can best be considered as a sudden demand on the individual for adaptation to a radically changed pattern of human relationships and the capacity to react to this change is influenced by past relationships all the way back to childhood In this respect there is no change more drastic in its effects on all within the immediate family circle than the birth of a new human being The emotional stresses with which the psychiatrists are concerned in the ætiology of psychiatric disorders are not hurricanes floods, wars and the other relatively rare cataclysms which the insurance companies refer to as 'acts of God' but the emotional stresses of adaptation to those suddenly and radically changed intimate relationships which, far from being rare are the inevitable lot of every human being

It will be evident that by far the most important agents of emotional stress in this sense are the ubiquitous phenomena of birth and death Because of this, all human societies from the dawn of history have evolved ceremonies and rituals to support their members through the stress of emotional adaptation which the beginning or the ending of a life imposes upon others and the stresses which arise at all those steps on the path between the beginning and the end in which the individual s relationships are suddenly and drastically changed Birth ceremonies, puberty rituals, initiation procedures marriage ceremonials, and burial rites are in fact the intuitively devised prophylactic measures by which societies temper the emotional winds that blow on those suddenly shorn of old relationships or forced to adapt to new ones In our sophisticated Western cultures these ceremonies tend to wilt under our scientific criticism of what we call superstition—and so we are left with the stresses but no communal mechanisms for helping us to adapt to them —unless like the *Times* with its obstinate and conservative sense of reality we can remember in our clinical practice that births deaths and marriages are front page news for the individual human being, and that politics and international affairs can wait until p 8

### RÔLE OF THE OBSTETRICIAN

Our Western societies have demanded of the obstetrician the utilitarian function of preventing death in childbirth and since the days of Semmelweis the obstetrician has lived up to this expectation with a success to which the maternal mortality rates of the Western world bear ample witness But the original social function of the folk midwife of a primitive tribe was I suspect, probably not that of the scientific obstetrician—to protect the woman and her child from death in childbirth—but rather to support the mother and her family through the processes of psychological adaptation demanded by a new birth Even this more modest function however may well have made its indirect contribution to the far more difficult tasks of modern obstetrics when we remember the extraordinary rarity in primitive peoples of primary uterine inertia, or failure of lactation—those two bugbears of Western obstetric practice

The Western science of obstetrics has excelled in the new function of the prevention of death; and yet perhaps in doing so at any rate in the half-century which has recently passed it has tended to forget the emotional needs of the mothers and babies who lived It is immensely to the credit of the specialty that the balance is now so rapidly being redressed and that some obstetricians having brought under control the physical hazards of childbirth are now turning their attention to the psychological stresses it entails

The current interest in the training of the pregnant woman for active participation in childbirth the development of rooming in ' and of self-demand feeding practices show that the obstetrician having relegated death to the position of a minor risk in childbirth is capable of continuing to develop his function of helper in a normal biological process by fostering the psychological readaptation for which that process calls

---

* From a paper read to the International Congress of Obstetrics and Gynæcology Geneva July 1954

### RÔLE OF THE PSYCHIATRIST

"But where," you may ask, "does the psychiatrist come into all this?" To which I can only reply "He comes in too late" He sees the end results of the failure of that adaptive psychological process—and he sees them at a time when the failures are consolidated in the form of an established neurosis or psychosis, when only extensive therapeutic endeavour can change the picture Yet it is evident to him that, before that state arose, in every patient's case there was a period of fluidity, of plasticity, when very simple measures might have tipped the scale in the opposite direction This was the period during which pregnancy and the birth of a child first threw on the family constellation a demand for psychological adaptation to which it finally failed to respond constructively At this period it is not the psychiatrist but the obstetrician and the obstetric nurse who have the opportunity for action, but perhaps the psychiatrist can help to train them to make the best of this opportunity

He can tell them something of the normal anxieties and psychological preoccupations of pregnancy, the deep archaic fears that are stirred by this primitive biological experience fears which seem worlds away, or perhaps I should say centuries away, from the everyday life of the Western world The idea of the "evil eye," for instance, so long ago discarded as a superstition in our societies, feels like a reality at some time or other to many pregnant women Mood changes that affect temporarily, but deeply, the woman's attitudes to her husband or her unborn child Her gruesome fears about her own body or that of her unborn baby All these are among the normal abnormal thoughts of many pregnant women

Ignorance of the natural history of the psychological aspects of maternity also causes problems for many a woman who suffers unnecessary anguish and sometimes a permanent twist of attitude as the result of the latent period of absence of feeling for her newborn child—not knowing how normal this is, and that within a few days or weeks her motherly feelings towards her infant will suddenly mature with overwhelming force

The psychiatrist can also offer to the obstetric worker techniques for resolving or dissipating such anxieties It is heartening to see that the skills developed by the psychiatrist in the field of group psychotherapy are beginning to be used by obstetric workers in therapeutic discussion groups for pregnant women and young mothers in which these normal archaic anxieties to which I have referred can be worked through

At this point some one might interject "Why bother? The average woman and her husband cope with the psychological readaptation to childbirth without our aid" To which the psychiatrist would be tempted to retort a trifle tartly that the same is probably true of the physical hazards of childbirth, and that, in the one field as in the other, it is during the antenatal period that we must try to discern those whose risk, either physical or psychological, is greater than the average Certainly some pregnancies raise greater psychological problems than others, either by virtue of the woman's previous experience of a pregnancy that ended in catastrophe, or —even more serious—where it was secretly self-terminated Most dangerous of all is probably the pregnancy which the woman failed to terminate Her previous personality is an equally significant factor The identification in the antenatal clinic of a woman with a markedly immature, dependent, and infantile personality is perhaps therefore as relevant a part of the antenatal examination of the future as the recognition of a contracted pelvis was in the past, both call for special antenatal prophylactic measures

All this, from the psychiatrist's point of view, is important enough with the birth of a normal infant, but it becomes doubly so with a dead baby or an abnc child A woman who has invested the emotions of nine months' pregnancy and a labour in what proves to be an abnormal child, is from a psychological standpoint, in great danger—and yet, at the same time, much more accessible to help than she will be six months later The person who can most easily help her, by virtue of her existing relationship with her, is her obstetrician Therapeutic discussion at this point may change the whole future development of the child by preventing the mother's relationship with him being wrecked on the scylla of rejection or the charybdis of guilt ridden overprotection

The obstetrician and psychiatrist have, I believe, a duty to collaborate to ensure that obstetricians of the future are well equipped, by the training we give them, to cover this new, and yet very old, aspect of their specialty

---

## SWEEP-FREQUENCY METHOD OF TESTING THE HEARING OF SCHOOL-CHILDREN

THE following statement has been prepared by Prof. A W G **EWING** at the request of the Medical Research Council's Committee on the Educational Treatment of Deafness

In a recent investigation it was found that approximately 70% of pupils in English schools for the deaf and partially deaf have suffered from their handicap since before the age of two years From the Ministry of Education's returns and from the results of recent surveys it seems that nearly all deaf children are admitted to special schools by the age of seven years, but that the ascertainment of partial deafness as a cause of educational retardation is at present less effective among children under seven than among those who are older

The sweep frequency technique has been shown to be a reliable and efficient method of making screening tests of the hearing of five and six year old school children A pure-tone audiometer is used and, when the range of frequencies that are used is extended from 250 to 6000 cycles per second early symptoms both of conductive and of perceptive deafness can be detected It has been established that a sweep check over this range of frequencies at 15 decibels above normal threshold of detectability is more thorough and reliable as a screening test than the use of word material (as in the test by gramophone audiometer) the loudness of which cannot be monitored satisfactorily for this purpose The fading intensities, called number test has been shown to be sometimes ineffective for the detection of high tone deafness

Audiometricians who have been trained to work with young children are able to make a sweep check of auditory acuity, as an individual test, at a rate of three minutes per child It has been shown that extraneous noise in a room in which a screening test of hearing is to be made should not exceed about 30 decibels The sweep frequency test can be made in a small room. When it is necessary to make screening tests of children's hearing in school buildings it is much less difficult to find small rooms that are quiet, in schools, than large rooms

The sweep frequency test can be made immediately or soon after children are first admitted to school, whereas the gramophone audiometer test, as normally administered, is a group test, in which children are required to write down numbers that they hear It cannot therefore be used with children younger than eight years The sweep frequency test is very valuable in screening out children who are likely to need hearing aids and special educational treatment before they have been exposed to the risk of educational subnormality as a result of defective hearing

A comparative study of the relative reliability of the sweep frequency and gramophone audiometer tests, when both were administered to six year old children individually, showed the sweep frequency tests to be superior The called numbers that are used in the gramophone audiometer test involve a constrained context and are therefore often recognisable by children suffering from loss of hearing to a significant degree

## HOSPITAL COSTING

The Hospital Costing Returns for the year ended March 31 1954, have now been published by the Ministry of Health[1] They cover some 2500 hospitals in England and Wales, and are based on the headings of the hospitals financial accounts. The general pattern of the tables is the same as in previous reports but the analysis is even more detailed and the returns from each hospital are now tabulated under some 47 headings A working party set up by the Minister is still deliberating upon a more informative system of costing meanwhile the costs for outpatients continue to be unavoidably included with those for inpatients, and in the calculations five outpatient attendances have again been taken as equivalent to one inpatient day—a questionable assumption as we have already pointed out[2] On the other hand the additional information does allow more just comparison to be drawn between hospitals of equivalent *status*

The accompanying table shows the steady rise over the last four years in the national average costs per week of patients in the main types of hospitals (the figures are adjusted for notional outpatient expenditure and exclude returns from teaching hospitals) For London teaching hospitals classified as general, the average cost (computed on the same basis) was £25 4*s* 2*d* in 1953–54 compared with £24 18*s* 8*d* in 1952–53 Equivalent figures for provincial teaching hospitals were £19 2*s* 9*d* (1953–54) and £18 13*s* 9*d* (1952–53)

HOSPITALS ADMINISTERED BY REGIONAL HOSPITAL BOARDS AND HOSPITAL MANAGEMENT COMMITTEES

| Classification of hospital | Year ended March 31 | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1951 | | | 1952 | | | 1953 | | | 1954 | | |
| | £ | s | d | £ | s | d | £ | s | d. | £ | s | d |
| General | | | | | | | | | | | | |
| 1–50 beds | | | | 12 | 11 | 9 | 13 | 13 | 6 | 14 | 7 | 8 |
| 51–100 beds | | | | 14 | 7 | 2 | 15 | 7 | 5 | 16 | 1 | 3 |
| 101–300 beds | 13 | 10 | 3 | 14 | 13 | 3 | 15 | 10 | 6 | 16 | 2 | 4 |
| 301–900 beds | | | | 14 | 11 | 7 | 15 | 12 | 1 | 15 | 19 | 1 |
| Over 900 beds | | | | 10 | 0 | 10 | 11 | 8 | 11 | 11 | 16 | 3 |
| All hospitals | 13 | 10 | 3 | 14 | 5 | 11 | 15 | 4 | 9 | 15 | 15 | 5 |
| Mainly general | 11 | 12 | 3 | 12 | 10 | 10 | 13 | 4 | 7 | 13 | 16 | 1 |
| Mainly chronic | 6 | 18 | 4 | 7 | 5 | 1 | 7 | 12 | 10 | 8 | 6 | 8 |
| Chronic | 5 | 15 | 5 | 6 | 0 | 0 | 6 | 11 | 6 | 7 | 0 | 2 |
| Convalescent | 6 | 15 | 9 | 6 | 12 | 11 | 7 | 11 | 4 | 8 | 3 | 0 |
| Isolation | 16 | 11 | 1 | 17 | 0 | 1 | 17 | 0 | 0 | 19 | 0 | [illegible] |
| Maternity | 16 | 9 | 6 | 16 | 19 | 2 | 17 | 13 | 1 | 18 | 0 | 5 |
| Mental | 3 | 15 | 11 | 4 | 1 | 1 | 4 | 8 | 6 | 4 | 12 | 0 |
| Mental deficiency | 3 | 11 | 4 | 3 | 17 | 1 | 4 | 4 | 4 | 4 | 8 | 11 |
| Orthopædic | 9 | 17 | 0 | 10 | 15 | 3 | 11 | 13 | 0 | 12 | 0 | 11 |
| Tuberculosis | 8 | 17 | 2 | 9 | 0 | 7 | 9 | 19 | 6 | 10 | 8 | 1 |
| Tuberculosis and isolation | 12 | 11 | 8 | 13 | 3 | 8 | 13 | 5 | 7 | 14 | 1 | 5 |
| Children (general) | | | | | | | 13 | 17 | 2 | 15 | 6 | 4 |
| Ear nose and throat | | | | | | | 14 | 6 | 4 | 15 | 5 | 2 |
| Eye | | | | | | | 12 | 9 | 3 | 12 | 15 | 4 |
| Eye and ear nose, and throat | | | | | | | 15 | 5 | 1 | 15 | 17 | 11 |

The costs vary considerably with the size of the hospital and with the regional area concerned. Thus in 1953–54 in the North West Metropolitan region the average cost in hospitals of 1–50 beds was £16 17*s* 6*d* per patient per week while in the same region the figure in hospitals with 301–900 beds was £20 9*s* 10*d* Equivalent figures for the Newcastle region were £12 1*s* 3*d* and £15 1*s* 9*d*

The Minister in drawing the attention of hospital authorities to the returns points out that in the past they have proved a useful stimulus to the elimination of extravagances and to the more efficient use of available funds Clearly they will serve their purpose even better when the long awaited improvements in methods of costing are eventually introduced.

# Points of View

## INSTITUTIONAL MEDICINE

*From the Posthumous Papers of*

SIR JAMES SPENCE*

It is I think, one of the inherent peculiarities of an Englishman and more particularly of a Northumbrian that if you scratch him he begins to brood over his *institutions* And *then from time to time he reforms* them. He is, as it were still in the atmosphere of those tremendous years before and after 1688, when our revolution was settled more by sincerity of argument than by force of arms and when there were men of the calibre of Halifax the Trimmer to hold the balance Now again in this century we are in the midst of another revolution which is shown by our concern about our institutions If we have neither the vigour which is an affair of the spirit, nor the means which is an affair of the intelligence to reform our institutions it will be a matter of interest mainly to the historians of the future but such a state of affairs will be cold comfort to those of us who believe that the excellence of civilisation is shown in the capacity of its citizens constantly to reform its institutions in order to meet its changing cultural needs. But change may be for the better or the worse, and in remembering this we should be guided also by Burke s admonition that merely to innovate is not to reform '

To be an institution means many things but on the whole the word has now a derogatory meaning It conjures up pictures of buildings and committee rooms of barracks and corridors of orphanages and museums and to call someone an 'institutional child is to speak half in pity and half in reproach I will try to refresh the meaning of the word by reminding you that an institution is people and not things An institution is the establishment and arrangement of human effort towards a common end It will stand or fall according to the value of this end, or purpose as we may call it and according to the means which are used to reach it The means are the government the administration and the arrangement for carrying out its work—three quite separate functions which must not be confused As the end never justifies the means, so these means or functions are all important By these standards most institutions neither stand nor fall but just flounder along because their end is forgotten or because their means are confused or inept You must forgive my presumption in placing these elementary thoughts in your minds before turning to the profession and practice of medicine which is now so involved in institutions that I must attempt to find a way through their maze

Seeking definitions for the foundation of an argument like this I go back to that early arch Englishman Thomas Hobbes—who was rare at definitions In discussing how the liberty of subjects is to be measured, he stresses the overriding need for government or sovereignty as he calls it and distinguishes between Sovereignty by Acquisition and Sovereignty by Institution The former is to govern through the seizure of power the latter is to govern by the covenant of one to another or of the many to the few This definition gives to the word institution the meaning I wish to convey Institution is to covenant that something shall be carried out and to transmit to someone the authority to arrange for it to be carried out I shall accept this definition when I mention the institutions which affect medicine and the disorders which beset them

---

* The opening passages of the presidential address given by the late Sir James Spence to the Newcastle upon Tyne and Northern Counties Medical Society in October 1953 followed by an outline of the rest of the lecture prepared from Sir James's notes

I have indicated that institutions may be good or bad, or good in parts, or just floundering along If they are bad there are usually three possible causes These are (1) that they do not know or see clearly what they are trying to do—or there are conflicts of purpose in what they are trying to do , (2) that they have not the will to do what they know they should do (which is a fault of government) , and (3) that they do not have the ways, and kind of people, to do what they want to do (which is a fault of arrangement or administration) Where arrangement or administration fails it is usually because there has been no clear definition of responsibility

The simpler the institution, and the clearer its purpose, the easier it is for it to be successful At one end of the scale we have simple institutions, like football teams, cricket clubs, ships' crews, and public schools, whose purposes are clear, and in which the division of responsibility is precise under arrangements which can be judged by results At the other end of the scale we see complicated institutions like trade unions, professional associations, regional boards, trade corporations, national coal boards, and city councils If they fail or flounder it is because their purpose is not clear or because their government and arrangement do not match their purpose

[Here the lecturer spoke of the definitive distinction between a service and an institution ]

I can go no further in this attempt to anatomise human institutions, but before I look at the institutions which affect medicine I will recapitulate in mentioning three aspects of them which may be worth bearing in mind

The first is the great increase in number and size of institutions in recent years This carries the danger that we are creating institutions beyond the capacity of the available intelligence, the available will, and the available morality which are necessary to maintain them

The second point, which arises from the first, is that the creation and maintenance of complicated institutions demand a particular kind of intelligence, personality, and education in those responsible for them The form of this education took shape in John Locke's famous essay, and the substance of it was given in our older universities, at a time when they were designed to give an education for responsibility This education was reinforced by a system in which the younger men knew intimately the older men experienced in the art of government In the aristocratic tradition this was still further strengthened by the concept of *noblesse oblige* If we were to seek modern examples of these mature craftsmen in the art of government of human institutions we could use John Anderson in our own day, and Robert Morant before him , but the weakness of our present situation is that it is impossible for a sufficient number of people to get close enough to men like Anderson and Morant to learn from their examples

The third point concerns the manners of those who take part in the affairs of institutions and by manners I mean *mores*, and therefore morality It is beyond question that the manner, or morality, of most of us towards a simple institution like our family or our cricket club tends to be of a different order from that we adopt towards complicated and impersonal institutions like British Railways or the Commissioners of Income Tax An appropriate morality is achieved satisfactorily in a good naval vessel, a good battalion, and a good university , but in the vast impersonal social institutions we are now creating the very opposite may happen Perhaps our fate is that our civilisation will flounder in the midst of the vast institutions it builds, but which it cannot maintain, for want of capable men They will then be like the dinosaurs—too big for their jobs, or too big for their shoes

* * *

There was need, Sir James continued, for careful study of the defects and disorders of the many kinds of institutions affecting the profession and practices of medicine—for the study of *clinical institutology*, or the morbid anatomy of medical institutions

Explaining what he meant by *medicine*, he described it as the fulfilment of a social contract or covenant between a professional man and another man who is sick or who fears he is sick The fulfilment of this contract was in giving advice, explanation, or treatment, or any combination of these The contract might be with a group of professional men, but in that case there was clear division of responsibility Personal responsibility was the essence of medicine—the patient goes to a doctor not to a board of governors or a clinical cure company—and the doctor's first responsibility was to his patient not to his employer

### *Types of Institution*

Among the institutions affecting medicine two kinds of *professional association* could be distinguished (a) those which are simply medical societies, and (b) those which have power over other people, such as the Royal Colleges with their diplomas and the specialist societies in America

Of these the *medical societies* came first, for many reasons Of all medical institutions they were the most moral—in purpose, in method of government, and in method of administration They had frailties rather than disorders, and these were all in the officers rather than the members

A third type of medical institution was *family practice*, whether by a group or by a single doctor Fourth we might have the *health centre*—but not yet He thought this would become a local service rather than an institution

As an example of an institution nearly perfect in type, he described the working of the *Medical Research Council* and its National Institute of Medical Research

Turning finally to the *hospitals*, he spoke of their development in four phases first, the founding phase (round about 1750) , secondly, the period when the hospital was the place of the predominant practitioner (1800–1900) , thirdly, the period when it was the jumping off ground for consultants—when practice was obtained through hospital reputation (1900–1930) , and fourthly the period when it became a centre for specialist services with development of peripheral specialist units

Of hospital problems, the first was size a hospital of up to 150–200 beds could be an institution, but above that size it was likely to become a service In speaking of organisation, he recalled his definition of institution as the establishment and arrangement of human effort towards a common end, and said that he knew of no example of a good hospital which has not been created through the good offices and good will of its medical staff Occasionally one might see a hospital which is very good but in which the medical staff appeared to play very little part in the government , but such a hospital functioned through the excellence of its component institutions It was a fault if the medical staff either cannot or do not give guidance to the governing body

The size and complexity of the large modern hospital made it a service rather than an institution, and much depended on the size of its constituent units The size of the unit in turn depended on the proper size of the team in charge of it, which (he suggested) should not exceed 10–12

The task of the teaching hospital was complicated by its additional responsibility for teaching and research nd here Sir James Spence expressed his regret at the ilure of the concept of the region with a university ospital at its centre *The position of the teaching hos* ital had become precarious through the growth of gional hospitals as specialist centres and through its onsequent loss of acute medicine and surgery and the iseases about which general practitioners most need dvice and help In his opinion it had been a grave istake not to make the teaching hospital a university stitution, giving it a local area in which it would e responsible for designing the entire hospital service t should be a central hospital for acute medicine, surgery nd fevers and with specialist annexes

### *he University Pattern*

Outlining the design of the teaching hospital—its ethodology its morality its style—Sir James Spence rew a parallel with the English university at its best ts three purposes—clinical science clinical teaching nd the care of the sick—were comparable to the three urposes of a university which are to advance scholar hip to teach students and to create a university life nd there need be no conflict between these purposes Ie believed that just as universities are free from the ontrol of the Ministry of Education, so teaching hos itals should be free from the control of the Ministry of Iealth.

In conclusion, he spoke of his faith in the future of ur universities through which England would endure They are big but they remain an institution Con ersely he had great fears for the future of hospitals, nd foresaw a day when the best of our young men will o into simpler and more satisfying institutions—otably general practice

## The Widdicombe File

### XXI MERE?

EAR JAMES

As young James no doubt will have told you by now is job seems to be in the bag There are the usual ormalities to be gone through of course but the old man kes the look of him, and I expect he'll be drawing his icroscope from our store and booking his six feet of ench in a month or so

There's a thing I want to talk to you about like a utch nephew though James Young James tells me—nd indeed it can be read between the lines of your last tter to me—that you're not in the least proud that he's llowing in your footsteps Which is a sad state of fairs, isn't it? But it's a symptom you know James, a disease very widespread among pathologists—an cessive modesty about our own science How many mes have I not heard you get up at some society eeting and begin in tones of abject apology Mr airman if a mere morbid anatomist might venture Mere *morbid anatomist! What you had to say* is always good sense often much needed good sense, d often as forward looking as any of the speculations minor sciences but it was in your view mere morbid atomy to be heeded but not honoured There are a w of the old generation of pathologists who believe in eir subject and a few of mine who think they've discovered it but most of those who fruited between o wars wear a blighted air of eternally apologising for e smell of formalin

There are two main reasons for this one historical but hemeral the other psychological and perhaps inescap le Historically we live still in the shadow of the down that followed the excessive pretensions of the rman school For well over a century, beginning with orgagni plain honest morbid anatomy was the master science of medicine We need go no further than the classic works of Addison Bright and Paget to admit that (Lord knows what *one would call the master science* nowadays the bacteriologists captured the fiery cross fairly from us somewhere about 1880 and the applied physiologists I suppose came next but which of a score of contending disciplines one should recommend to the aspirant for fame I don't know which I suppose is a healthy sign ) But not least of the diseases of western civilisation for which we can blame Mittel Europa is the exploitation of morbid anatomy Virchow was a very great man second to none of our champions except Pasteur and perhaps Lister in their century And Rokitansky and Cohnheim and Waldeyer and others were also mighty men in their generation But they and their followers built up a fantastic machine which went on under its own steam long after its original inspiration had run down Leaving Virchow himself on one side, the German Austrian school made at the time rather less than their fair share of discoveries in pathology but they wrote ten times as much about it Who hasn't struggled with those terrible German articles of yesteryear (did Ewing really read all the references in his *Neoplastic Diseases* I wonder?)—fifty pages of unsignposted text with two useless illustrations, ten of the pages devoted to cell by cell description and the rest to polemics all based on perhaps one new fact that it's a day's work to locate Even today *Virchow's Archiv* but that's another story What wouldn't Matthew do to that so expensive journal!

By about 1890 the view that all good pathology was German was thoroughly fashionable and for the next forty years all good pathologists went to Germany or Vienna to sit at the feet of one Herr Professor or the other I have a vision of you James in your impressionable youth, standing among a cosmopolitan crowd of devotees ranged in two lines down the hall of Aschoff's Institut at Freiburg while the Chief marched between the rows waving a bloody heart beneath your noses and drove *into your avid minds an unalterable dogma* There was a long period when nine tenths of the pathology in this country was secondhand German pathology It's not surprising that in time the non pathologists reacted rather violently Morbid anatomy isn't all of medicine, morbid anatomy for its own sake is only quite a small part of medicine When the Bayliss Mellanby Lewis school of physiological medicine attacked (the Eumenides come to punish our *hubris*) we crumpled badly Much of their more virulent darts were mere Sir Tommy rot but still we crumpled and to be a 'mere morbid anatomist' has been a term of derision ever since

That's mere temporary insanity: we are already past bottom dead centre and on the way up again But there is one disability under which pathologists labour and always will We are all shy men Granted many of us overcompensate and behave with excessive heartiness or are even aggressively rude it is still true that at bottom we are shy Let me expound The satisfaction derived from the practice of medicine by its best practitioners resides chiefly in the employment of a highly personal intellectual skill for the immediate uncomplicated benefit of their fellow men It is possible to feel to the full this generous fervour and yet to find that faced with the individual patient one loves him less than one should and this is often due not to misanthropy, but to a simple failure of the capacity more born than made for the establishment of that instant rapport with other men which is so essential to the successful clinician I do not think we should be ashamed of admitting that in this sense most pathologists are clinicians *manques* In one way or another from those who have frothed up into the cloud-cuckoo land of psychiatry to those who have withdrawn into the surgery of one organ from pure researchers and statisticians to editors and members of

Parliament, many of the brightest ornaments of our profession are refugees from the clinical front line But the isolation of the laboratory tends to exaggerate the primary defect, and pathologists do on the whole seem even to themselves to be a rather ungracious lot compared to many of our colleagues But the fault, dear Jacobus, lies not in our science but in ourselves, that we are unglamorous Let us not therefore repine, and grovel, and look hangdog Glamour of a sort is necessary to the clinician to the pathologist (unless indeed he teaches undergraduates, when it will help him for the first week or two of term till they find him out) glamour is as incongruous and unnecessary as an orchid buttonhole on a coal-heaver

There's something to be said for every branch of the work we do Even post mortems It's a mucky job, and hard work, and few normal people I think really relish its actual doing—and fewer still find it easy to confess to their fiancées or their children just how they earn that part of their living But post mortems can be infinitely exciting real life is always better than the best detective novel

> " World is suddener than we fancy it
> *World is crazier and more of it than we think*
> Incorrigibly plural "

—there are few better illustrations of Macneice's dictum than that ever-surprising four dimensional puzzle presented by the body at the end of a lifetime of varied assaults and defences and few satisfactions greater than that of making the pieces fit And the job is vital enough the P M room is almost the only independent conscience left to a hospital nowadays A hospital whose consultants never see a post mortem has a rottenness at its core and it is often the pathologist's fault if they don't (What a knife edge must we often walk between the carping Charybdis of the cheap jeer at a wrong clinical diagnosis, and the soothing Scylla of the " my colleague, right or wrong " attitude—but how worth while it is to find it )

Important though post mortems are, the whole orientation of most pathological departments has been altered in the last twenty years by the steady rise of biopsy work Histopathology used to be chiefly the art of telling the surgeon what kind of lump he had taken out—an esoteric affair of limited practical importance, with few skilled practitioners The tremendous increase in the use of the biopsy as a means of diagnosis—by physicians even more than surgeons—has profoundly altered this We have far more work, and what there is is a great deal more interesting and valuable Our relation to our hospital is becoming curiously similar to the radiologist's. He sees more patients, and sees them sometimes in motion we see a little deeper, and on the whole our diagnoses are more reliable but we get more and more like each other, and what might be called our public relations and administrative problems are very much his What a game histopathology is !—one of the most difficult arts of medicine, wearisome without end to learn, exasperating to the end, yet ever and again with its rewards of sudden illumination

That's all very well, you may say, James , the routine's valuable and very much more interesting than it looks but how about research ? Nowadays you can't hit the headlines without estimating the lacrimal excretion of radio ytterbium-labelled preposterol, or inventing a five dimensional tensor vector E E G , or growing the virus of onychogryphosis in crocodile's eggs How can I convince people that research in straight pathology is worth while ? Simply enough The answer is just as Vesalius had to come before Harvey, morphological research has always to precede physiological but the second stage of this process is always the more spectacular of the two—simply because it scoops the pool provided by its predecessor There's a singul apt parable provided by the reputations of those two g American cardiologists, Maude Abbott and Helen Tau Maude Abbott worked forty years on congenital hear and produced an Atlas which everyone has heard though few read Helen Taussig sorted out what t anomalies Maude Abbott had described meant in term function, and she and Blalock scooped a sensational p It was wonderful work don't imagine for a mom abate anything in admiration of it, but don't take M Abbott for granted Without the anatomical ground it couldn't have been done

If the surgery of congenital hearts had never b invented, Maude Abbott's Atlas would hardly have b heard of outside her specialised field The same app to all exploratory, observational, recording resear One can never know what part of the field is going to illuminated suddenly by the searchlight of pract application An observational research is never who done No barber shaves so close but another finds wo and moreover observations are like translations from t Greek, and need to be done afresh for every generati Whoever believes that there is no more worth w research to be done in morbid anatomy is either a f or blind We make discoveries slowly, but they st This business of Barr's about sexing nuclei—what object-lesson it is in the way things can stare us in t face for years without ever being seen ! How many ot things must we be looking at every day without seei them ? Morbid anatomy was dead, they said, in t early '30s but the Kimmelstiel Wilson kidney and t *diabetic retina, the pathology of crush kidney,* vir hepatitis, retrolental fibroplasia, and molluscum sebaceu are all stories which have broken since then, and in th list I have included only a few common important th We progress, slowly perhaps, but genuinely and i cease to progress the whole edifice of physiolog research will go on without noticing it much for te twenty years, and then lose itself in a maze of the that have lost that feet on the earth check which supply better than anyone else can

We accept too easily the idea that observati *research and the experimental method are two* diffe things (I see it is fashionable nowadays to ascribe t invention of the experimental method to Grosset Bishop of Lincoln perhaps I shall protest less w next Peter junior calls me " big-head ") An experim is not something you do with spectrometers or guinea or Geiger counters if you are merely amassing d you may use ten isotopes and a thousand mice with doing, truly, an experiment If you make a hypot based on evidence, and then set about collecting n data to test that hypothesis and abide honestly by result, you are *acting* in the best experimental tradi even if your new data are acquired by mere inspectio organs or microscopical slides or even the library I the attitude of mind, not the technique, that matter

Which is not to decry technically experime research (Our mice have got ectromelia again, tho which would give me an excuse for any amount decrying ) But that is open to all men, even thou may still call itself pathology I am speaking only o kind of research that is inherent in the activities of who call themselves pathologists on hospital staffs *I think it's good and necessary*

I've lectured you long enough Don't let me puff up with false pride, James Stay humble, but be hu rather before the infinite complexity of man's body before the pretensions of other disciplines Let model be Jeanie Deans rather than Uriah Heep will do our best to keep young James proud of be pathologist

Yours,
PETER DA

# In England Now

*Running Commentary by Peripatetic Correspondents*

MOST doctors wisely refrain from giving medical advice n second hand information about symptoms, but I ave lately had two vicarious patients whose progress uggests that advice based on vague information is ometimes worth acting on

The first was a middle aged man who developed mysterious alling attacks with loss of consciousness. These caused grave oncern many serious possibilities were discussed and phenoarbitone was prescribed A letter from his wife read out t my breakfast table gave a perfect description of cough yncope *A recent paper on this subject was therefore sent* o the patient's doctor and no more was heard of these ttacks.

I heard of the second patient when an English doctor sent ne a letter she had received about a relative in America who was becoming mentally disturbed and was being treated or hysteria. A letter written by the patient herself showed mong other evidence unmistakable evidence of dysgraphia wrote to the English doctor suggesting that a left hemisphere erebral tumour was likely and that a good brain surgeon hould be consulted without delay This advice duly crossed he Atlantic and was acted on with remarkable speed despite onsiderable resistance from the patient's advisers. Two and half weeks after the first letter was written a cable was eceived in England Successful removal benign brain tumour size of egg Apparently the patient was critically ill at the time of operation and a malignant tumour seemed likely but at operation a large meningioma was easily removed from the surface of the brain and complete recovery followed

In medical work it is sometimes the simplest acts which are of most consequence while some of our present-day complex procedures too often pay insignificant dividends

* * *

Opinions vary on the usefulness of oral penicillins; and hospital doctors, who can inject penicillin in a few seconds with the aid of nothing more strenuous than a fountain pen see the problem a little differently from heir friends in general practice

Last week I prescribed oral penicillin for a small boy with bronchitis I was horrified to find later in the day that the medicine had proved so much to his liking that he had taken the whole bottle-full at a single dose Appalling thoughts of overdosage *poisoning and stomach* washouts passed through my mind After ordering an ambulance I rang the local hospital to warn them of he impending arrival. The house-physician on hearing hat 12 million units of penicillin had been swallowed y a boy of seven gave it as his opinion that that was no earthly good—I should *inject* a million units straightaway

* * *

I took Justin our young anæsthetist down to the nd of the jetty and we began to prepare our lines. The golden grey mullet were moving darkly in the black green waters below and I hoped for a good catch Everything seemed right—the sea was fairly calm the wind low and southerly the sky flecked with high cloud everything seemed right—that is except Justin who has a natural genius for getting into trouble He seems to live on he brink of chaos and is always more than half inclined to all into the abyss On our last fishing expedition—the Hospital Anglers Outing—he had walked quietly and with infinite dignity off the edge of the weir into the river and emerged many minutes later when the rest of s had abandoned hope more than 100 yards downstream ith his pipe still clenched between his teeth and his ot and rod in his hands To the immense edification f the party he picked his way out of the water attached new fly to his line and walked back along the weir o the exact spot from which he had fallen; he then ast with consummate grace and skill across the tail of e fish run as though nothing had happened There always an impeccable aristocracy about Justin's ehaviour of which no-one is more keenly conscious han himself

Standing on the jetty behind us was a young visitor from London immaculately over-dressed in the mock Edwardian style of the day He smiled indulgently as Justin was trying to restore order to his line Justin scowled I was about to drop my live bait into the sea when a cormorant, attracted by the fish suddenly swept up from the waves and alighted on the railing between Justin and me In a last despairing effort to unravel his line and sinker Justin was swinging it round his head in ever-increasing circles. The line went spiralling round the cormorant's neck and in a moment the bird was captured I was too amazed to speak The Edwardian, deeply impressed had lost his smile Cor blimey!" he gasped, Is that the usual way to catch em?'

Justin who appeared unmoved, looked slowly all the way down his long patrician nose 'And pray,' he said, what method would *you* use?

* * *

Beer may be best at home, but as all the world knows Americans like soft drinks. The reason for their addiction to Coca Cola is obscure Possibly the secret lies in the fact that each bottle contains about $2^1/_2$ grains of caffeine Whatever the reason coke machines are to be found everywhere—in canteens, shops, factories, outpatient departments hospital corridors outside operating theatres, and even in post-offices They are of ingenious design Insert your coin and down comes a refrigerated bottle and your change An opener is handy, and a crate rack for empties stands at the side of the machine. At medical conferences the manufacturers supply the stuff free and in unlimited quantities They deserve their ultimate *dividend for this contribution to the prevention of sleep* and dehydration

* * *

Few doctors can put their hand on their heart and say I have never given myself drugs ' but many can say, with Sir Joseph Porter 'Hardly ever Aspirin once in two years for a headache and an occasional barbiturate *for sleeplessness is my normal indulgence but last week* two nights poor and disturbed sleep had lowered my morale and a day's hard work strengthened my determination to have a really good night. So at 19.30 (I always use the 24 hour clock) immediately before supper I took two capsules from one of my boxes of samples. All was well until I was about to tackle some apple-pie with cream (the Queen of my puddings) when my wife noticing my vacant expression accused me of being drunk I had enough sense to tell her of my misdemeanour After some unjustifiable resistance and supported on both sides I was led to bed muttering as I went that I must send the firm a testimonial I was undressed and fell into bed and a sound sleep disturbed soon after by the visit of my doctor who comforted my family and gave me a good prognosis. He was fully justified for the next day I did my daily round and tasks. By a curious coincidence a friend from abroad came to stay She had not recovered from a severe operation and asked if I could prescribe something for her insomnia With what rapture I presented her with the remnants of my sample

* * *

Enthusiastic junior staff sometimes lack the verbal discretion of their more mature colleagues Our surgical registrar and *his house-surgeon lately had occasion to* write up their separate sections on a form for cremation and it had been agreed that the H.S would collect dues from the undertaker Later he breezed into the casualty room and with no heed to a crowd of attentive patients cried: Cremation form—here's your two guineas With commendable presence of mind the S.R said 'Ah yes thank you—just managed to scrape in third I gather—a good race A financial transaction that might well have caused misgiving among the bystanders was given the verisimilitude of one which no-one present would do other than approve

I always know what to give a lady said my bus conductor (not to me unfortunately) First I give her a Guinness and then I give her a gin-and-cloves—a lovely drink for a lady—and then I give her a good strong port"

# Letters to the Editor

## USE AND ABUSE OF ANTIBIOTICS

SIR,—I fear your correspondents of Dec 18, Mr Grainger and Mr Elliott, have been misled by the necessarily brief account which you gave of my remarks at the conclusion of the joint meeting of the sections of general practice and medicine at the Royal Society of Medicine You report that I had been " struck by the fact that 50% of the drug bill of every large hospital was for penicillin " We were discussing antibiotics, and I was referring not to the total cost of drugs, but to the expenditure on antibiotics, and stressing that despite the criticisms which had been levelled against penicillin, it remained the most widely used of these drugs On the last available figures, every large hospital in my own region (which I had no reason to doubt reflected the general picture) was spending approximately 50% of its total antibiotic costs on penicillin despite its decrease in price, and the advent of newer antibiotics Precise figures for the whole region and for the United Liverpool Hospitals are as follows

*Liverpool Regional Hospital Board*

| *Year* | *Antibiotic cost (% of total drug cost)* | *Penicillin* | *Streptomycin* | *Chloramphenicol* | *Aureomycin* | *Other antibiotics* |
|---|---|---|---|---|---|---|
| 1950–51 | 29 % | 67 % | 33 % | — | — | — |
| 1951–52 | 40 % | 51 % | 49 % | — | — | — |
| 1952–53 | 40 % | 48 % | 30 % | 13 % | 9 % | — |
| *1953–54 | 36 2 % | 41 % | 29 % | 10 % | 11 % | 9 % |
| *The United Liverpool (Teaching) Hospitals* | | | | | | |
| 1952–53 | 32 9 % | 61 % | 12 % | 18 % | 9 % | 0 3 % |
| *1953–54 | 30 1 % | 57 % | 11 % | 12 % | 12 % | 8 % |

* The returns of 1953–54 have become available since the symposium and show a small fall in the cost of penicillin

My plea for discrimination in the use of especially the newer antibiotics was not based primarily on economy, but on their potential hazards both to the individual and to the community

Liverpool HENRY COHEN

## PSYCHOLOGICAL ASPECTS OF UTERINE DYSFUNCTION

SIR,—In his article of Dec 18 Dr Cramond concludes that " psychiatric methods of prediction and prevention in the antenatal period would have no effect on the occurrence of uterine dysfunction " While this may well be true of the psycho analytical approach it is not a logical deduction from his paper, nor is he entitled to conclude that " fear, emotion, and anxiety play no part in the outcome of labour from the practical obstetrical point of view " Neither his control nor his " dysfunction " group were given any sort of physical or psychological preparation unless we count the eighteen who attended " talks on pregnancy and childbirth " There remains a possibility therefore that uterine function in both groups might have been improved by good preparation and that some of the " dysfunction " group might have avoided their forceps and sections

The fashionable rejection of preparation for childbirth is too often based on slender grounds, the preparation having consisted solely of a few " relaxation " classes and a lecture or two Numerous workers have found a more thorough preparation of value Dick Read, while one can dispute his physiology, undoubtedly influenced the course of labour in his patients

In France workers at the maternity clinic of the Pierre Roques polyclinic, basing their work on Pavlov's theories of central nervous physiology (perhaps Dr Cramond will find these equally obnoxious), are also demonstrating the very real influence of what they call " psycho prophylaxis " on labour Their methods include (*a*) explanation of the facts of pregnancy and labour, (*b*) explanation of the rôle of tradition and false attitudes in lowering the cortical threshold to pain by implanting false conditioned reflexes, (*c*) an attem to replace these false attitudes with healthy ones, (*d*) instructions in methods of muscular relaxation a respiration Finally, great stress is laid on a factor usual neglected in this country—the need for the const presence throughout labour of trained staff to assist t parturient woman in the application of her lessons B these methods some 80% of obstetrically normal moth are delivered without the use of analgesics The aver duration of labour has diminished and the interven rate has dropped sharply in this clinic since the intr duction of these methods[1,2]

Dr Cramond concedes that preparation may allev " mental pain," however this is defined I feel there i evidence that it can do more than this One does n dispute the multiple ætiology of uterine dysfunction claiming that preparation for childbirth can remove, some women, one cause for it In addition preparati can provide for the majority of women having n deliveries an experience always tolerable and enjoyed

London N W 5 ANTHONY RYLE

## HARDENED FATS AND LUNG CANCER

SIR,—Dr Nyrop's suggestion (Dec 18) that th consumption of margarine may be a factor in t causation of lung cancer is based on such slender irrelevant, and sometimes inaccurate arguments that must be challenged

His first point is that the unsaturated essential fatt acids may play a part in protecting the body a carcinogenic agents The only real evidence whic Dr Nyrop quotes for this is the work of Deuel et al,[3] in which rats deficient in these substances were found t succumb rather sooner to carcinogenic doses of X ray *How they react to chemical carcinogens is quite unknow* More important, deficiency of essential fatty acids h never been shown definitely to occur in man

Secondly, Dr Nyrop states that the hydrogenati of fats to produce margarine and shortenings " eliminates essential acids " This is not true Margar contains something like *twice* as much essential fatt acids as butter, and shortenings may contain up to f times as much as butter[4] Rats have been reared f 25 generations (*equivalent in man to some 750 ye* on margarine as the source of dietary fat, and h shown as good health, vitality, growth, longevity, a *fertility as those fed on butter*[5]

Finally, Dr Nyrop falls into the common trap " correlation equals causation " Margarine cons *has increased, so has cancer of the lung, ergo, the f* causes the latter But it is not only the consumpti of margarine which has increased, there has also be *an increase in looking into television and in the* us synthetic fibres for clothing, either of which could equ well be accused of causing bronchial carcinoma T *argument could be used just as reasonably to prove* th *lack* of association between consumption of margar and the incidence of cancer of the lung In countr where there has been little *or no rationing*, the aver consumption of margarine is inversely proportional income, we should therefore expect a similar relati ship between cancer of the lung and economic class fact, the relationship between lung cancer and econo class is slight and its direction differs in men and wom in any event, it does not fit in with Dr Nyrop's br thesis Again, margarine consumption in Holland

---

1 Ryle A *Med World Lond* 1954 80 36

2 *Rev nouv Méd* 1954, no 3 (special issue)

3 Deuel H J Chang A L S Kryder, G D Bingemann *Science* 1953, 117 251

4 Deuel H J Greenberg, S M Anisfeld L Melnick *J Nutr* 1951, 45 535

5 Deuel H J Greenberg S M, Savage E F *Ibid*, 1 42 239

ppreciably higher than in Britain but the incidence of ung cancer is approximately half that in Britain

Summarising then, we may say (1) whilst there is ome evidence that deficiency of essential fatty acids enders animals more susceptible to X ray cancer there s no evidence that they are more susceptible to chemical arcinogens, (2) deficiency of essential fatty acids rarely f ever occurs in man (3) hydrogenated fats like mar arine contain more of these acids than the fats such as utter, which they replace in the diet, and (4) the ncidence of cancer of the lung is not generally higher n those groups with higher margarine consumption

JOHN YUDKIN

## OCCASIONAL BRONCHOGRAPHY

SIR,—I was interested to read Dr Glendinning s article in your issue of Dec 18 The method he describes I have used essentially unchanged except as regards the actual local anæsthetic for the past sixteen years or so with complete satisfaction in very many more patients than the occasional case '

Atropine injected a half to one hour before the examination commences is invaluable and I do not hesitate to increase the dose from gr $^{1}/_{100}$ to $^{1}/_{75}$, or even gr $^{1}/_{50}$ in the chronic bronchitic whose mucous membranes are generally much more moist than those of the average person

As a recent refinement I find that a tablet of amethocaine (gr $^{1}/_{2}$) given to suck a few minutes before the spraying begins gets over the gagging ' of the sensitive or nervous patient who resents the approach of a throat spray Incidentally I find 2% plain lignocaine ( Xylo caine ') quite adequate (which increases the safety margin till further) and by using a De Vilbiss syringe can get my spraying direct on to the cords After intubation in the chronic bronchitic I inject 1 ml of the lignocaine solution down the tube a minute or so before following t with the opaque medium

There are a few patients who have the knack of saying e ' quite well with a small catheter between their vocal cords, and I find the simple trick of aspirating air up the catheter confirms the correct lie of the tube If he tube is in the trachea aspiration is of course easy and ompletely devoid of resistance and injection is equally ffortless with the tube in the œsophagus aspiration of air s either impossible or intermittently possible against a eeling of resistance

The virtue of the method Dr Glendinning has described s that in the hands of the tyro the worst that can happen s a failure of the examination, and with reasonable care satisfactory examination is carried out with little listress to the patient In the hands of the expert it ives an opportunity for detailed filling of any area or reas without hurry and, if necessary under screen ontrol

Central Middlesex Hospital
London, N W 10

F PYGOTT

SIR,—Dr Glendinning provides a valuable description of a very pretty bronchographic method and suggests hat patients would much prefer tracheal intubation to ricothyroid puncture I have used a similar method of ransnasal blind intubation for some years and although agree it is free from the dangers of cricothyroid punc ure, patients who have been subjected to both methods ay without exception they much preferred the crico hyroid route Dr Glendinning does not mention the lifficulty I have sometimes found in passing the tube hrough the conscious patient s nose and in making it url down into the pharynx Questioning patients and ractice on myself suggests that this is the most uncom ortable part of the procedure

FRANK RACKOW

## A FILM ON MENTAL NURSING

SIR,—I read in your issue of Dec 18 the report of the film *The Troubled Mind*, and looked forward to seeing it on the television programme that night Having seen it I find my mind very troubled

The object in producing this film was to show it to the general public in order to attract recruits to mental nursing Surely sight must have been lost of the effect this film will have not only on the parents of recruits, but also on patients who may require treatment in mental hospitals and their relatives

For many years now a great deal of time has been spent and much work has been done in enlightening the general public on mental illness, and encouraging the mentally ill to come voluntarily into hospital for treatment That this effort has been justified is shown by the fact that between 70% and 80% of patients now come in voluntarily some hospitals claiming an even higher percentage of voluntary admissions

The general public the relatives of the mentally ill and the sick patients themselves nearly always conceive the mental hospital as being populated by patients obviously deranged obviously disturbed and obviously requiring segregation The fear of entering a mental hospital is so often based on this conception that admission is refused on the grounds that the illness is not bad enough or will become worse as a result of mixing with such patients.

This film in my opinion serves only to confirm these misconceptions, and I now fear the results It is obvious that patients could not be used in the film but the rôles played by the members of the staff of Shenley to depict patients were poorly portrayed and grossly over acted If patients themselves could have been filmed I am sure that they would have appeared more normal and that even the scene showing the disturbed ward would not have included (in any one day) all the deranged behaviour shown In the incident of the male patient refusing occupational therapy was it necessary to indulge in facial twitching in order to be recognised as a patient ?

Hysterical attempts at suicide impulsive smashing of windows furious digging in the gardens deliberate destruction of shrubs were all shown as the common everyday behaviour all manifest at practically the same time and even those patients walking in the grounds of the hospital were openly mental ' Except for the scene of the small group in the room saying they had come voluntarily on whom only a few moments were spent, there was no suggestion of the normality of which as you rightly point out, newcomers to mental hospitals remark But these are normal people.

Why must electroconvulsion therapy be shown as distressing to the new nurse when modern treatment using muscle relaxants routinely produces practically no visible signs of convulsion ? Why must occupational therapy be represented by cane work ? In a fairly recent comedy film the hero is shown doing cane work to infer his admission to a mental-observation ward much to the amusement of the audience

More student mental nurses are very sorely needed They are required to be trained to nurse the mentally ill and to help in the treatment of the acute cases and in the nursing and rehabilitation of the many long stay patients who for lack of sufficient staff tend to be withdrawn idle slovenly and incontinent Nurses are required in larger numbers so that each can have a small group of patients for stimulating interests for encouraging habit training for occupational and recreational therapy for nursing the physically ill and for encouraging the aged to be ambulant The concern for patients must continue to be fostered and not as in the film trained into apparent indifference as shown by the ward sister towards the suicide attempt

I doubt very much the value of this film in recruitment The film is courageous but it does not show the training and work of a mental nurse in true perspective It does harm in placing before the public a picture of mental hospitals which is not in accord with conditions today I fear it may only indirectly help to solve the problem of the shortage of nurses in mental hospitals—that is, by discouraging from voluntary admission a large number of patients in need of treatment

Bexley Hospital
Kent

## A WORD WANTED

SIR,—May I, with some diffidence, point out that, in his letter in your issue of Dec 18, Dr Todd is in error The meaning he ascribes to πρός is in fact that of πρό and it is from this word that πρωί is derived

There already exists an excellent Greek word, πρόσκοπος ("seeing beforehand"), the English form of which would be "proscopic" Since the true superlative of πρό is πρῶτος (first), an alternative and more emphatic adjective would be 'protoscopic'

DOCTOR'S HUSBAND

## PATIENTS' DAMAGES

SIR,—Most of your readers will agree that the great majority of cases of medical negligence in which no special clinical or pathological knowledge is required can be effectively and fairly dealt with under the present system It is in the vitally important minority of cases where such knowledge is essential that the courts are placed in the invidious and impossible position of having to assess clinical judgment in retrospect The remarkable change in legal interpretation as a result of the 1946 Act seems to result in pronouncements which, as I pointed out in my original letter (Oct 30), often seem to be inspired by the view that this *legislation guarantees* the patient not only treatment but cure

I was at no time enamoured of the idea of taking medicine outside the law my concern was wholly—and not at all incidentally—with the ethical sequelæ of this change in judicial interpretation, and it was solely for the safeguarding of these principles that medical representation was advocated in the *investigation* of such negligence Legal convenience was not my concern, but a leading article in the *Times* of Dec 18, while not concerned with professional freedom, does suggest an arrangement by which both medical and legal interests might properly be served

> "Administrative tribunals, whose decisions are enforceable as law, have no doubt come to stay They do, as a rule, dispense fair judgments—comparatively cheaply—over a great range of subjects on which the Queen's judges have, and would claim, little competence to pronounce The need for them arises from the overruling by legislation of private rights, generally property rights but sometimes rights of personal liberty, for the sake of public advantage"

It is ironical to note that the letter instigating this exposition was concerned not with advocating the establishment of such tribunals, but that there should be easier appeals from their decisions Medicine is thus not one but two steps in arrears!

This brings the argument full cycle The problem remains, but it is only fogged to those of us who are good administrators or indifferent doctors The evolutions of both medicine and the common law possibly through regard for each others' special function, have traditionally been in parallel, and the results have dovetailed for the welfare and well being of the community But now they are to some extent in collision, and there may be many of your readers who are concerned that the standard medical contribution to medicolegal controversy seems too often to be that of gratuitous apology which, rightly or wrongly, presents the picture of a profession in flight from its principles, and content to accept t clinical intuition of Her Majesty's judiciary

## TUBERCULOSIS IN IMMIGRANTS

SIR,—I should like to endorse most strongly the opin of Dr Sevitt (Dec 18) that the solution to the prob of how to protect the health of the Irish immigrant in close and friendly cooperation between the British Irish health authorities *Attempts at compulsion* unnecessary and probably inapplicable, moreover, are likely to arouse strong resentment and so befog t real issues I can see no clash of interest whatev between the Irish and ourselves over this matter, it in their interest that their subjects over here rema well and in ours to keep them well Let us thrash our mutual difficulties amicably, sensibly—and togeth

Clare Hall Hospital,
Barnet
NORMAN MACDONALD

## TRYPSIN INHALATION IN BRONCHITIS

SIR,—I was very interested to read the letter fro Dr Oswald and his colleagues in your issue of Dec 4

I do not think that trypsin has a place in the treatme of the ambulant chronic bronchitic, but, if effective, i would have a very definite place in the treatment the acutely ill emphysematous patient who is unable t raise sputum because of its tenacity It would also help in the management of the emphysematous patient who having got over his acute respiratory infection, becom chronically anoxic simply because he cannot get rid o the tenacious sputum Chronic anoxia results in mor and more lethargy and inability to concentrate and he less desire to cough In fact the mental state may such that the patient is thought to be just "pl awkward"

Exsufflation with negative pressure[1] is used in th U S.A in the treatment of these patients, as is inte mittent positive pressure breathing,[2] which also help to get the aerosol deeply into the lungs. Both metho require the cooperation of the patient, and they costly and, so far as I know, unavailable in this countr

I have used 'Trypure' in a patient aged 57 who w admitted on Oct 14 in semicoma due to an acute respirator infection complicating a severe degree of emphysema. H wife said that he always had difficulty in raising sputum O admission arterial blood analysis showed a pH of 7 25, a pCO of 69 mm, and an oxygen saturation of 49% One m later the oxygen saturation had risen to 71%, the pH 7 33, and the $pCO_2$ 56 3 mm At this point, although cyanos he was mentally clear

Since then his cyanosis has increased, owing, I think, to inability to get rid of the sputum, and his mental state h deteriorated Arterial blood analysis now shows a pH o 7 30, a $pCO_2$ of 62 5 mm, and an oxygen saturation of 45% Although the $pCO_2$ in repeated blood analyses has shown tendency to rise slightly the oxygen saturation has remain almost constant He will not tolerate oxygen therapy Trypu has been used, therefore, to loosen his sputum It has be given through a Collison inhaler using 8 3 mg in 2 5 ml o the buffer on the first, double the amount of both on th second, and three times the amount on the third day Th dosage was used in order to avoid waste since trypure i supplied in 50 mg phials with 15 ml of diluent and wh mixed must be used at once On the following day I divid the 50 mg into three equal parts and gave three inhalatio at 4 hourly intervals

Although there was no immediate improvement in h general condition he has raised more sputum on these s subsequent days, and 5 days later his mental condition becam quite clear and the arterial blood showed a pH of 7 29 $pCO_2$ of 60 mm., and an oxygen saturation of 60% Whethe this improvement will be maintained or not I do not know but all the evidence suggests that it is due to the action o

## CONTINUOUS INTRAVENOUS OXYTOCIN

SIR —The article by Mr Holmes in your issue of Dec 11 is of great interest to those attending women in abour

At the obstetric clinic of the University of Geneva[1] imilar experiments were carried out in 1949 on 91 cases nd the conclusions reached were comparable to those f Mr Holmes It was felt however that a 5% glucose olution was to be preferred to physiological saline or the following reasons

(*a*) The heavy demand made upon the uterine muscle uring labour especially after oxytocin administration equires an increased intake of glucose An intravenous drip s indicated especially in cases where feeding by mouth is eing withheld in view of possible anæsthetics

(*b*) Oxytocin increases liver glycogenolysis. The hepatic lycogen reserve may be considerably lowered and it is herefore advisable to replace the loss by additional intake of lucose

n no case was venous thrombosis observed

London N W 3
RACHEL WERBLOWSKY

## RASH ON THE SOFT PALATE

SIR —I was struck by an illustration in Dr Holzel s rticle of Nov 20 of a soft palate rash and I said at nce Alexander s sign In early 1919 there appeared n the bulletin of current medical literature issued to the R.A M C a précis of an article by a Russian physician Alexander who described a soft palate rash as a diag nostic sign of true influenza This rash he affirmed to be on the soft palate and to be punctate and erythematous with some œdema which outlined the junction with the hard palate It was unlike that noted in infective mono nucleosis in being rarely petechial

As we were in the middle of an outbreak of true nfluenza at that time I was soon able to convince myself that the rash always did occur in the first few lays of true influenza and that it did not occur in he common forms of febrile rhinitis &c which are commonly called influenza

Since that time I have found that this rash is of great help in the differential diagnosis of true virus influenza But I have never heard of any other physician who vas acquainted with it

## MASS TUBERCULIN TESTING

SIR,—In your otherwise admirable leader of Dec 18 I was alarmed to see the re birth of an old idea that mass miniature radiography units should be diverted to mass tuberculin testing—a course which can only lead to a reduction in the total output of these valuable units at a time when more and not less chest radiography needs to be done. Probably less than 30% of our adult population have ever had an X ray examination of their chests and one of the problems before mass radiography is to include in its scope those not previously X rayed Ideally this would be the whole of the remaining 70% but with the limited resources available it is to be expected that only selected groups can be surveyed In my view this can now be achieved only by an intensive and nation wide propaganda campaign on a scale at least as powerful as that devoted to diphtheria immunisation or the sale of detergents It is a practical fact that the limits of local propaganda have been reached

The essential element of mass radiography which distinguishes it from other forms of chest radiography is the speed at which the film passes the shutter of the camera Nothing must be allowed to slow this speed Although the staff of the present units have considerable experience in approaching the public and in the organisation of mass campaigns, their function is in no other way connected with tuberculin testing and the two should not be confused Thus though there might be some virtue in a loose association between a tuberculin testing team and a M M R. unit in order to pool certain resources and experience any attempt to fuse the two would be to the advantage of neither and the detriment of both

The level of tuberculin positivity is still high enough in the adult population to merit mass X ray examination without previous tuberculin testing and although it is often claimed that the discovery of a positive tuberculin reactor leads to the discovery of a source case it is equally often forgotten that the discovery of a case by M M R. also leads to another one by proper surveillance of contacts Mass radiography has a vast task still to do ; let it not be diverted to other pursuits till that task is finished

One further point If mass tuberculin testing is to be done, then the sooner the better and before the scene becomes shrouded in the mists of tuberculin positivity created by B C G

London W 1
F D BEDDARD

SIR —In your leading article Mass Tuberculin Testing you say that the proportion of London school children positive to tuberculin is startlingly low

I would have thought that this would have been an expected finding in view of the efforts made both nationally and locally against tuberculosis. What is most significant is the figure you give of 75% of the 6 5% positive reactors in the mid Wales survey which were traced to a human source This draws attention to the inestimable value of the tuberculin test as a weapon in the hands of the epidemiologist in the tracing of spreading infection

In the past when the number of positive reactors in the population was high the use of the tuberculin test was very much limited in this field ; but now that there is such a high proportion of negative reactors we must be careful to make capital of this position in the control of tuberculosis Mass B C G immunisation will destroy this present advantage and until we have more valid statistical evidence of the value of B C G we would do well to hasten slowly

Manchester 3
IAN G TAYLOR

SIR —I was interested in the article by Dr Carroll Palmer and his colleagues and by the leading article in your issue of Dec 18

Unless the reasons are very strong, I think it would be a great pity to replace the 10 T U intradermal tuberculin test by one of 5 T U In this country, largely as a result of the Prophit Survey and the recommendation of the Ministry of Health (memo 324/B C G ), the 10 T U Mantoux test has been in general use as a screen test and many of us are now beginning to feel some confidence in its interpretation

I am in full agreement with your leader and with the W H O Expert Committee on Tuberculosis, who insist " that B C G vaccination campaigns should be centrally organised and made part of the general public health programme " , but I am sure the suggested method of carrying out this work—namely, the employment of one mass radiography unit in each region—is not practicable Consider, for a moment, a single group of the community—children in their 14th year The X ray examination and B C G vaccination of these children must be carried out at school during the spring or autumn terms, the summer term being fully occupied with examinations, sports, and other activities

Mass radiography of this group in Cornwall (approximately 4000 children, scattered among 175 schools) occupies the mass radiography unit for nine weeks The population of Cornwall (341,463) is approximately a tenth of the population of the South-Western Region, which includes Devon, Cornwall, Somerset, Wiltshire, Gloucestershire, and parts of Dorset It would, therefore, be quite impossible for one mass radiography unit to carry out mass radiography, Mantoux testing, and B C G vaccination of this single group of the community in the time available Moreover, the mass radiography unit is a highly skilled and specialised unit, adapted for its purpose It would be uneconomic to employ it in routine tuberculin testing and B C G vaccination

For the past two years, Cornish school children in their 14th year, whose parents are willing (approximately 85% consent), have been passed through the mass radiography unit, tuberculin tested, and given B C G vaccination where indicated

The mass-radiography unit visits 11 centres at which the children from the surrounding schools are assembled Tuberculin testing is carried out by the assistant county medical officer or the school medical officer, assisted by the school nurse, as part of their routine duties Three days later, a chest physician visits the school to carry out B C G vaccination An exception is made in smaller, isolated schools, where all the work is done by the assistant county medical officer or the school medical officer The sharing of this preventive work by the director of the mass radiography service, the chest physician, and the local authority medical officer is, I think, of great value in integrating the two sides of the tuberculosis service It has the added economic advantage of not requiring any additional staff

County Hall,
Truro

E R HARGREAVES

## PEPTIC ULCERATION IN SOUTHERN NIGERIA

SIR,—Mr Konstam's observations (Nov 20) on the incidence of duodenal ulcer in Southern Nigeria and the influence of diet open a wide field of interesting and useful research , but I do not think he should so lightly discount the psychosomatic side, because the outward appearance of dignified calm and placidity of the average Yoruba, be he peasant or townsman, is deceptive Having once worked as medical officer in charge of Adeoyo Hospital I found the Yoruba to be highly strung and sensitive, and surrounded by complexities of tribal, family, and personal life which would give the average European an easily explained ulcer The " simple peasant " in the South does not exist He is just as worried about his cassava crop as Mr Jones is over his overdraft The market woman at the hospital gate with a [illegible] pile of groundnuts for sale in front of her is very likely the owner of a fleet of produce lorries and four-figure deals with the Cocoa Marketing Board.

The examination of physiological fluids is child's compared with understanding the intricacies of psychosomatic side of the African

## A BLOOD-TRANSFUSION PUMP

SIR,—A rotary pump for use with all forms of venous therapy was fully described by Mr Victor R in his book, *Blood Transfusion,* published in 1939 was described and illustrated again in Mr Keynes's recent symposium on the same subject

This type of pump provides a simple and effic method for the rapid replacement of blood when th indicated

London, S W 1

ERNEST LANDA

## GOITROGENIC HAZARD OF COBALT

SIR,—We have read with interest the letter fr Dr Gairdner and his colleagues in your issue of Dec 1 We fully agree that cobalt should not be added to preparations for general use, but we feel that it would unfortunate if clinicians were discouraged from pre- ing a drug useful in the prevention and treatment of anæmia of prematurity and other iron-resistant anæm

We have reported [1] the use of cobalt sulphate in premature infants (maximum dose 20 mg daily for fo weeks), and a further paper dealing with its use various iron resistant anæmias in childhood is in press

Over 200 other children, both prematures and with infection, have been successfully treated and toxic effects noted in any case The majority of our were treated from three to four weeks, but in some t ment was continued for eight weeks with no adv results

There is now a considerable literature referring the hæmopoietic action of cobalt in both man animals with no reference to goitrogenic activity the paper quoted by Dr Gairdner, and we feel that beneficial effects of cobalt fully justify its contin use in selected cases under careful supervision

## PROLONGED PREGNANCY

SIR,—In your issue of Dec 11 Mr Stenhouse has ask two questions and I should like to reply

When I saw my patient for the first time at 38 wee the presenting part was not engaged and the long firmly closed primiparous cervix suggested that conditi were most unfavourable for an attempt at induction labour I was anxious to avoid anything but spontane delivery, it seemed certain that the position improve with delay for a week or two, and the norm onset of labour was awaited with confidence Q naturally I did not anticipate the actual sequel L when labour was in progress, it became clear that deliv was obstructed With the lowest part of the ceph pole scarcely advanced to the level of the mid pel and with the certainty of seriously abnormal struct still at or above the pelvic brim, embryotomy was in my view a procedure to consider As events prov it would have been extremely difficult and theref dangerous

I have lately found a reference to an analysis of an cephaly by Mr Percy Malpas as long ago as 1933 [2] Th was postmaturity in 9 cases out of a series of 44, and one instance the pregnancy lasted for 374 days

## INNOCUOUS TEMPORARY IMMOBILITY

SIR —The condition which was described under the lo Night Nurses s Paralysis in your last issue can cause ich alarm when temporary immobility occurs for the st time and the sufferer is unaware of its harmlessness I have drawn attention in the past [1–3] to the occurrence this condition in persons engaged in other occupations more especially printers Since immobility can occur ring the day as well as the night and in persons other an nurses, the name is clearly a misnomer though it s been in use for many years, and it was used in lectures en to nurses at some mental hospitals in the earlier rt of this century

The condition is widespread and occurs in all climates have known it on board ship in the Arctic Ocean and places as far apart as Montreal Macclesfield Gibraltar d India

In a recent investigation which I conducted 60 male d female nurses were questioned and 25 (42%) knew the condition, 19 (32%) having suffered from one or ore attacks In a previous inquiry [1] of 67 male and male nurses 27 (40%) were aware of its existence but ly 12 (18%) had suffered from attacks The latest vestigation did not add to the 16 conditions from hich the immobility must be distinguished [2] but it led a fuller appreciation of the existence of partial attacks, attacks in those other than nurses and of the further ngers to the subject during the course of an attack

*Partial Attacks* —In 3 cases the ocular muscles were e only ones involved

A matron reported that from time to time when reading the day or night she was unable to move her eyes from e end of one line of print to the beginning of the next. This s so frequent that she thought it was a normal occurrence everyone A female nurse said that her eyes became fixed any part of a line of print when reading at night and a le nurse who also suffered from generalised immobility up to 5 minutes duration timed by the clock, stated that at ght his eyes became fixed for about 30 seconds or so at y part of the line

An observer said that on 3 occasions, he saw a male nurse and stop writing for a few seconds. Suddenly the nurse und he could write again During the attacks the nurse s able to talk and make other movements. One person s able to smile in an attack and 2 were able to talk although distinctly in one case

An observer noted that the male nurse whom he was ho ing was apparently watching him and turned his head wards him but was unable to move until the observer took ld of his arm when he suddenly jumped up

*Attacks in Non nurses* —There were 2 additional finite attacks and 1 doubtful attack in this investiga on

A warrant officer who was sniping in front of his trench in acedonia as he had done many times previously found that though his finger was on the trigger and 3 Germans in his ght he could not fire nor did he answer the telephone beside m until it had buzzed three times. He was asked why he had t fired He then did so

A sergeant was sitting leaning back against a tree in France 7 A M when an officer approached The officer said Get , Sergeant get up but he was unable to move although front of his men The officer had left before he was able to e but the sergeant apologised to him later

The doubtful attack involved a radar operator on a ship o although he saw an object on his screen was unable to port its presence to the bridge The officer on the bridge w the ship and asked him why he had not reported This s not been classified as a definite attack because no other rson was in the radar cabinet and the operator might have en sleeping

*Occurrences During Attack* —A night nurse in a mental spital said he was sitting down when he saw a patient approach him with a chair The patient struck him with the chair and the nurse was unable to defend himself The nurse watched the patient approach so the possibility of immobility due to fear cannot be excluded, although in mental hospitals the nursing staff are accustomed to dealing with troublesome and dangerous patients

This identification of partial attacks raises the question of cause Previously an attack comprising immobility of the legs alone was the only partial attack recorded This further inquiry shows that small portions of the motor system can be affected The site of the failure is obscure, but in view of the observation that small jerky movements may occur before full movement returns it seems that some impulses can get through to the muscles from consciousness As in many cases only one attack has occurred over 30 40 or more years, the condition does not appear to be a permanent psychological condition, such as hysteria This immobility may be due to defective transmission at the myoneural junctions although it is hard to see why only certain junctions should be affected in some cases or why in one man all voluntary muscles were affected on some occasions and only the ocular muscles on others But myoneural block seems to be the most likely explanation particularly since the condition usually occurs when the subject is stationary

## INTRAMUSCULAR IRON

SIR,—Dr Jennison and Dr Ellis in their article of Dec 18 conclude that local reactions to iron-dextran are seldom important and general reactions very mild We have had two severe reactions recently

The first wa in a man of 54 with ulcerative colitis and anæmia, who was given three 2 ml intramuscular injections of the iron dextran solution on alternate days After the second he complained of local soreness and after the third he had pain in both buttocks and fever to 102 F Over the next forty-eight hours, the outer parts of the buttocks became painfully swollen, red tender and indurated and the inguinal glands grossly enlarged and tender No further injections were given and the condition settled down completely within eight days without suppuration or the use of antibiotics. There was a past history of skin allergy which suggested an allergic basis for this reaction.

The second case concerned a boy of 17 with steatorrhœa and anæmia. He received 1 5 ml of the iron dextran solution intravenously At once he became flushed distressed and restless; bradycardia was noted, and a few minutes later he complained of severe pain in the loins which gradually settled in $1^1/_2$ hours.

It seems therefore, that this iron dextran preparation should be given further extensive trial before its general use is advocated

The London Hospital E 1 IAN P ROSS

## SMALL-BOWEL DISTURBANCES AFTER ABDOMINAL OPERATIONS

SIR,—Your report of Dec 18 mentions a statement by me at a meeting of the surgical section of the Royal Society of Medicine when I gave the figure of 8% for the prevalence of atrophic gastritis after partial gastrectomy My comment was an unprepared reply to the unexpected compliment of a question by the president and I would be glad to extend it

In the past eight years I have gastroscoped an ave
of just under 225 patients a year and the prop
these examined for post gastrectomy symptoms h
fairly steadily (excluding one year when th
333 patients when we made special exam
a week of hæmatemesis) from 0 7°
1954 Of the last 53 gastrectom
atrophic gastriti It would have b
this proportion as a percentage
negligible Professor Witt

earlier in the same meeting 2 of my patients had severe hypochromic anæmia (atrophy confirmed in 1 by biopsy), and a minor group of post-gastrectomy syndrome may be attributed to gastric mucosal atrophy

May I add an example of operative disturbance of small-intestinal function I would have quoted if I had had the presence of mind ? About 1908 a girl, aged about six, was severely burned and developed a stenosing duodenal ulcer Sir Henry Souttar found it necessary to do a gastro enterostomy, and she recovered About 1942 I treated her for microcytic anæmia, and about 1946 for œdema and hypoproteinæmia Shortly after discharge she returned with acute obstruction of the small intestine due to a band apparently connected with her previous operation This was divided and she has apparently remained well since It seems as if obstruction disturbed iron absorption first, protein absorption next, and finally the total arterial supply of the bowel

Hove Sussex W A BOURNE

## STRANGE LANGUAGES

SIR,—During the late war the Army Education Corps put out several useful booklets on foreign languages In view of the large number of Maltese, Somalis, Greeks, and Cypriots entering this country, could not the Ministry of Health publish similar pamphlets, obtainable on demand, for doctors near docks, &c ? They could contain colloquial speech and popular medical terms They would be more useful to me than my extra chair for an interpreter—and a " no smoking " sign in nine tongues

Mile End,
London E 1 N D WAYNE

## MECHANISM OF RAYNAUD'S PHENOMENON

SIR,—Lewis established that cooling of the fingers produces vasoconstriction, followed by vasodilatation [1] He maintained [2] that excessive vasoconstriction alone was the cause of Raynaud's phenomenon, but later observations have failed to support this view

Hertzman and Roth,[3] investigating a mild case of this disease, showed that although vasodilatation did not follow vasoconstriction when the patient's finger was placed in water at 15°C, vasodilatation did ensue when the water was colder (8°C) Greenfield and Shepherd [4] showed, moreover, that when healthy persons placed their fingers in water at 0–6°C blood flow in the digital arteries almost ceased (rapid dilatation followed after 5–10 minutes) It has also been found [5] that the vessels *of healthy persons*, and of those with Raynaud's disease, respond equally to adrenaline

Using the calorimetric method of Greenfield and Shepherd,[4] we compared the vascular response to cold in 20 patients suffering from Raynaud's syndrome with the response in a control group of 20 healthy persons Each subject first immersed his hand for 10 minutes in a water bath at 25°C and thereafter held his finger for 15 minutes in a calorimeter at 9 5°C [6]

We observed that

(1) The degree of initial vasoconstriction was the same in the two groups

(2) In the control group dilatation ensued after 4–6 minutes in 18 cases, during the 7th minute in 1 case, and during the 8th minute in another, in the patients with Raynaud s syndrome no dilatation occurred in 13 cases during the 15 minutes, and in the remaining 7 cases it occurred later, and to a lesser degree, than in the controls

This suggests that the essential difference between healthy persons and those with Raynaud's syndrome is in the capacity of their digital circulation to respond to the stimulus of cold by vasodilatation We attribute this to a local vascular defect in the mechanism dilatation

No noxious agent is known which increases the resp of vessels to constrictor agents and at the same leaves unaffected the mechanism of dilatation Bu has been observed that vasodilatation caused by co the perfused hind limb of a cat is abolished by so cyanide [7], that iodoacetic acid prevents reactive h æmia and dilatation due to nitroglycerin [8], and the sensitivity to acetylcholine of the vessels in a perf rabbit's ear, and the synthesis of acetylcholine, are decreased by complete sympathectomy of the vessel

The mechanism of dilatation, it seems, depends metabolic processes in the vessel wall, and any ups these processes will disturb the mechanism Some upset, we believe, is responsible for the absenc vasodilatation in Raynaud's syndrome

Institute of Industrial
Hygiene, Budapest. L MAG
G OKO

## AN UNUSUAL CASE OF SHINGLES

SIR,—Herpes zoster can be a difficult enough pro in the emotionally healthy patient, but when the dition occurs in a neurotic patient the interval (us a few days) between pain and rash may be an embar ing time for the doctor

A patient of mine, a man of 59, who is prone to ne symptoms, complained of pain in the right lower ches hypochondrium There were no abnormal signs—wh the usual finding in this case The pain persisted and gat strength for the next eight and a half weeks, during time he had repeated examinations by me, he consul naturopath, and finally saw a surgeon who ordered a graph of the chest and a cholecystogram, which were normal Neither the surgeon nor I could be drawn the diagnosis, though the naturopath had a shot at cystitis

The doctor patient relationship gradually worsened approximately sixty one days after the first consult when a characteristic herpetic eruption appeared distribution of the pain

The illness had not yet exacted its full toll, as the lesion and the post herpetic neuralgia incapacitated hi a further fifteen weeks

London S E 26 R N JACKS

## VENEREOLOGY AND DERMATOLOGY

SIR,—We note with concern the advertisement you published for the South East Metropolitan Reg Hospital Board on Dec 18, concerning a vacancy for sultant combining the two specialties of venereolog dermatology This follows a similar appointment was made some months ago by the East Anglian Reg Hospital Board These two special subjects hav points of contact For a number of years general p has favoured dissolution of a union which has no to recommend it beyond administrative conven and which, when it was common practice, aff adversely the standards of both subjects

As the result of this policy, which we comm registrars who have been appointed to departmen venereology or dermatology are being trained as sp ists in their respective fields and have had no opport of acquiring specialist knowledge of the other sub As the result they are ineligible for the appoint which you advertised

We suggest that the institution of such a com appointment is a retrograde step which is unfair to men and women working in these subjects and must ably to inferior standards of work in one or other st depending upon who is appointed to the vacancy it seems highly undesirable that these considerations d be regarded as less important than *administrative* nience

M. PICKERING PICK

## CANCER OF THE LUNG

R—On Feb 12 last the Minister of Health in a ten answer, stated he had received advice from the ding Advisory Committee on Cancer and Radio apy on the question of the relationship between king and lung cancer In his statement the Minister ared that it must be regarded that there is a relation and that there is a strong presumption the relation is causal He added that other factors may be ating—e g., atmospheric pollution—and that it is rable that young people should be warned of the risks arently attendant on excessive smoking and that it ld appear that the risk increases with the amount ked particularly of cigarettes

his report on the State of the Public Health in 3 the chief medical officer of the Ministry of Health ribes the inexorable march of cancer of the lung as ysterious May I suggest that this description is leading and is apt to discourage those who have ence with the community from giving the advice ffered by the Minister to young people

ranted that the specific carcinogenic factor has not n isolated as yet there is no real mystery associated h a condition *that in 1953 was responsible for 27%* ll male deaths from cancer

ouse of Commons
London S W 1

BARNETT STROSS

IR —May I support Dr Joules's plea in your Christmas y issue for honesty in facing the implications of the parently causal relationship between cigarette smoking l cancer of the lung ?

The community suffers from a mass addiction to the g of tobacco and is bombarded with advertisements *all those with an interest in maintaining this addiction* We are ill served by the chief medical officer, who may be regarded as the High Priest of Preventive Medicine, if he suggests in an official report that the cause of lung *cancer is akin to the mysteries of religion* The *march of* this disease will certainly be inexorable if the interests of the tobacco trade and the revenue are allowed to obscure the authoritative warning that should be given to the public

Barnet, Hertfordshire DOUGLAS MCCLEAN

## QUESTION TIME

### End of Agene

Replying to a question Mr HEATHCOAT AMORY Minister of Food said that he had now received a report from the subcommittee set up under the chairmanship of the chief medical officer of the Ministry of Health, to consider flour improvers A detailed experimental study had been made under the Medical Research Council The methods of flour improvement which had been examined were agene chlorine dioxide, potassium bromate ascorbic acid, and an aeration *process.* The experiments had confirmed that agene treated flour when fed in large quantities caused fits in dogs and had shown that none of the other improvers tested did the same Since other methods of flour improvement existed which had not produced these symptoms in animals the Government were of the opinion that, although no ill effects in man due to the use of agenised *flour* had been established effect should now be given to the decision taken in 1950 to discontinue agene

In view of this decision the National Association of British and Irish Millers had agreed to recommend their members to discontinue the use of agene and to give an undertaking that the equipment for treating flour in this way would be removed from their mills by December 31 1955 Some delay was inevitable because new equipment had to be obtained to treat flour by other means. The National Association of Flour Importers had similarly agreed to recommend their *members to ensure that no flour treated with agene would* be imported by them.

The further investigations undertaken by the Medical Research Council had revealed some differences between the effects on flour of the other methods of improvement but the effects demonstrated were not sufficient to require the discontinuance of any of the other flour improving processes. These methods of flour improvement would continue to be kept under close scrutiny in collaboration with the milling and baking industries.

### The Case of Mrs Christofi

Replying to questions on the case of Mrs Christofi Mr GWILYM LLOYD GEORGE the Home Secretary said that Parliament had on many occasions recognised the undesirability of pressing the Home Secretary to disclose the reasons why he did or did not tender advice to the Crown with regard *to the exercise of the prerogative of mercy in a capital case* The principal medical officer of Holloway prison had stated in a report dated Oct 5 1954 that he had formed the conclusion that Mrs. Christofi was insane but was medically fit to plead and to stand trial A copy of that report was furnished to the defence

In view of this report he had appointed three distinguished and experienced doctors to conduct an inquiry in accordance with the law The three doctors reported that the prisoner was not in their view insane and they added that in their view she did not suffer from any minor mental abnormality *which would justify them in making any recommendations* on medical grounds relevant to the question of a reprieve

After full consideration he came to the conclusion that there were no sufficient grounds for interference with the due process of law It would be contrary to long-established practice and as he thought open to considerable objection to disclose any advice tendered to the Home Secretary in a case of this kind by the trial judge or to disclose the terms of the medical report submitted by the statutory inquiry and he was not prepared to make these documents available There was no electro encephalograph examination of Mrs. Christofi as she would not agree to the examination being *made*

### Clinical Experiments at Hospitals

Replying to questions, MISS PATRICIA HORNSBY SMITH, parliamentary secretary to the Ministry of Health, said that hospital authorities were given power to conduct research by section 16 of the National Health Service Act, 1946 Individual clinical investigations were undertaken on the authority of the clinician in charge of the case, and the Minister had not complete knowledge of the extent of all the work in progress at hospitals Such investigations involved medical and ethical problems which were not susceptible of control by regulations

### Refunds of Prescription Charges

Replying to a question, MR OSBERT PEAKE, Minister of Pensions and National Insurance, said that from Oct 1, 1953, to Sept 30, 1954, the National Assistance Board refunded rather more than $9^{1}/_{4}$ million shilling charges for the dispensing of prescriptions A small number of these refunds were made to people not receiving a regular weekly National Assistance grant

### Monopack Hearing-aids

Replying to a question, MISS HORNSBY SMITH said that large scale clinical trials of a new 'Medresco' model, capable of being used in either monopack or duopack form, were to be held in the New Year with the coöperation of schools for the deaf and partially deaf If these proved successful, it ought to be possible to begin mass production about the end of 1955 It was proposed to supply miniature batteries for use with the aid in its monopack form free of charge for children, but adults who wished to use the aid in this form would need to buy batteries for themselves They would, of course, still be able to obtain the larger batteries without charge

### Mass Radiography

Replying to a question, MISS HORNSBY SMITH said that up to the end of 1953 the 68 mass radiography units had made 13,396,538 examinations, in about 5% of which some abnormality, not necessarily requiring treatment was revealed

### Orthodontic Treatment for School-children

MR ANGUS MAUDE asked the Minister of Education how many orthodontic specialists were available, full or part time, for the treatment of children in England and Wales under the school dental service —SIR DAVID ECCLES replied There were the equivalent of 17 full time officers, employed exclusively on orthodontic treatment, in the school health service on June 30, 1954, the latest date for which information is available This is an increase of the equivalent of 4 full time officers in the last two years The majority of school dental officers undertake some orthodontic treatment

### Hospitals and Dental Treatment

MISS HORNSBY SMITH replying to a question, said that the work being done by all grades of hospital dental staff, other than house officers, at Dec 31, 1953, was the equivalent of 3803 sessions weekly The total number of beds allocated to consultant dentistry at that date was 249

### Pulmonary Tuberculosis among Student Nurses

MR SOMERVILLE HASTINGS asked the Minister what percentage of student nurses in their first year developed pulmonary tuberculosis in 1953 —MISS HORNSBY SMITH replied I regret that this information is not available

### Birth-control in the Colonial Territories

MR T REID asked the Secretary of State for the Colonies in which of these Territories any system of teaching birth control to the people had been established —MR A T LENNOX BOYD replied So far as I know, no Colonial government has established any such system, but voluntary organisations are at work in some Territories, and in Singapore a government grant is made to such an organisation

### Industrial Health

Replying to a question MR HAROLD WATKINSON, parliamentary secretary to the Ministry of Labour, said that the advisory committee on industrial health would be an advisory body The scheme for the development of industrial health services including any necessary surveys, would be carried out through the Factory Inspectorate which possessed wide powers under the Factories Acts

### Lead Poisoning in Rotherham

ON Dec 20 the medical officer of health for Roth
Dr J A Gillet, was told that two twin boys of 3
Rotherham, admitted to the Children's Hospital, Shef
that morning, had been diagnosed as suffering fro
poisoning He also learned that a younger brothe
had died in Rotherham General Hospital on Dec 1
cause of death being given, after a post-mortem ex
nation, as status epilepticus due to idiopathic epile
He got in touch with the family doctor and heard
details of the history of the three cases Arrangem
were then made for the inspection of the area where
children lived by members of the staff of the Rother
health department It was found that old vul
car-battery cases were being used for fuel in some ho
It seemed that a scrap-dealer, after removing the
plates, was either selling or giving the cases away
nearby residents

Dr Gillet and members of his staff visited the home of
three children and found the grandmother, together
son and a younger married daughter and her baby, at
The old lady, who was edentulous, anæmic, and con
complained of a metallic taste in her mouth The son
no symptoms, but there was a suspicious blue line on
gums The daughter and her baby had no signs or
of lead poisoning In the meantime the chief sanitary insp
had found old battery cases in the coal house and had
told that they were burning them for fuel Samples of
cases and of the resultant ashes were taken for examinati

The police arranged to broadcast a message warning
holders not to burn any car-battery cases, and further
was obtained from the local press

During a house to house visit in the district, the n
and addresses were collected of all the occupants of
where vulcanite cases had been burnt The source of sup
the cases was stopped

It was then learned that a child of 5 who lived in
same area had died on Nov 21, the cause of death
given as cholæmia and infective hepatitis Arrang
were made for two brothers of this child to be
and they were later admitted to hospital suffering
lead poisoning

In view of the danger of lead encephalopathy,
has a far more serious effect on children than
poisoning on adults, it was decided to concentrate at
outset on the children in the affected district A
ments were made with the pathologists of the Pu
Health Laboratory, Sheffield, and of the Mo
General Hospital, Rotherham, to take a blood-count
film of all children exposed to risk, and this inquiry
on Dec 23 Up to the present 127 children and
adults from 41 houses are known to have been expo
The arrangements for blood tests are being cont
the hospital On Dec 22 medical officers from the he
department visited the affected houses and examined
adults, where necessary blood tests were arranged.
circular to all medical practitioners in the district was
out by hand on Dec 22 informing them of the outbr
and of the arrangements made for the examination
suspected cases

As to the disposal of the ashes and old cases, it
happened that the house refuse was collected from
affected district on Dec 21, and a considerable am
was therefore removed A special collection was org
as a further precaution and over 3 tons of cases and
were collected and removed on Dec 22

The lead may have been absorbed through the
(an unlikely route), by inhalation of ash or fumes
off by the burning cases, or by ingestion of food
taminated by dust and by handling the casings and
taminating food with unwashed hands Some of
younger children may have sucked a piece of the ca
Further investigations are proceeding

### Third Quarter in Scotland

In the quarter ended Sept 30, 1954, the inf
mortality rate of 24 per 1000 live births was the l
yet recorded in Scotland, and 8 below the five-
average Neonatal deaths numbered 16 per 1000

ths, 8 less than in the corresponding quarter of 1953 e birth rate was 17·7 per 1000 population—0·4 below e five-year average. Stillbirths amounted to 20 per 00 total births The death rate (10·3 per 1000 popu ion) was 0·2 above the average Deaths from tubercu sis amounted to 17 (respiratory 15) per 100 000 pulation compared with 21 (18) in the third quarter of 53 and a five-year average of 36 (31) There were 206 aths from malignant disease per 100 000 population— more than in the corresponding quarter of 1953 and above the five year average

## Obituary

### ELIZABETH CASSON

O.B.E., M.D. Brist., D.P.M.

Dr Elizabeth Casson, founder and for many years irector of the Dorset House School of Occupational herapy died in Bristol on Dec. 17

She was born in 1881 the third daughter of the late ajor Thomas Casson of Denbigh and she was a sister Sir Lewis Casson She was educated at St. Mary's ollege, Paddington and later studied housing management In 1908 she joined Octavia Hill's stalwart helpers Southwark and seemed to have found her life's work But conditions in South London showed her all too clearly that her tenants, as well as their tenements, needed repairs At the age of 30 she surprised her friends by taking her matriculation and beginning to study medicine

She graduated M.B. in 1910 and soon afterwards joined the staff of the Royal Holloway Sanatorium, Virginia Water In 1922 she took her D.P.M. and in 1926 she proceeded to her M.D. degree. In 1927 she was awarded the Gaskell prize

She herself has described how she came to realise the impor ance of occupation as a form of therapy

I found it difficult to get used to the atmosphere of ored idleness in the day rooms at the mental hospital. hen one Monday morning when I arrived at the women's ards, I found the atmosphere had completely changed and alised that preparations for Christmas decorations had egun The ward sisters had produced coloured tissue paper nd bare branches, and all the patients were working happily groups making flowers and leaves and using all their rtistic talents with real interest and pleasure I knew om that moment that such occupation was an integral part f treatment and must be provided

At Holloway Sanatorium she found a tradition of rafts and games entertainments, sports exhibitions ere all held regularly But it was all voluntary and no ork was prescribed by the medical staff On a visit o the Gart Naval Hospital in Glasgow she saw real occupational therapy for the first time in Dr (now lr) David Henderson's small department. Later she isited the larger department at Bloomingdale Hospital n New York She continued to seek out all the hospitals n England where the idea was gaining ground including ayland Sanatorium and the Lady Chichester Hospital in righton In 1929 she left Virginia Water to open a esidential clinic at Dorset House on Clifton Down near Bristol She was determined to arrange a full time lanned day for all her patients, and from this grew the Dorset House School of Occupational Therapy Soon fterwards a small department was opened at the Bristol eneral Hospital to show how occupational therapy ould also be used for patients with physical diseases.

The work continued to develop steadily and in 1936 he inaugural meeting of the Association of Occupational Therapists was held at Dorset House Shortly before he war the staff of the school helped in the planning nd opening of the Allendale curative workshop and Dr Casson reported in our columns in 1941 on the first 40 cases treated there (*Lancet*, 1941 ii 510)

With the war Bristol became an unsuitable place in which to run a school, and after some months of anxious negotiations Dr Casson arranged for her students to move to Barnsley Hall Hospital Bromsgrove After the war the school found new quarters at the Churchill Hospital in Oxford but Dr Casson continued to act as medical director and paid frequent visits from Bristol In 1951 she was appointed O.B.E.

F. S. C. writes: The memory of Elizabeth Casson will be cherished not only as an able psychiatrist and charming colleague, but also as the founder of the first school of occupational therapy in this country Soon after the late Sir Robert Jones had demonstrated the value of the curative workshop, she saw the need for trained personnel and recognised that, besides a knowledge of suitable crafts, the therapist must understand the nature of illness and how work therapy could help patients with both mental and physical disorders back to health From her own resources she established the Dorset House School of Occupational Therapy and sustained it by her teaching forthright leadership, and generosity throughout the difficult period of evacuation and expansion during the war until it was safely established under an independent board of governors of which she was a member Occupational therapy today owes a great deal to the foresight and example of Elizabeth Casson

### WILLIAM JOHN HANDFIELD HASLETT

Kt., M.R.C.S., J.P.

Sir William Haslett, who died on Dec. 17 at Weybridge, was for many years a valued member of the Middlesex County Council. His public service was inspired and directed by his medical training and experience and as chairman of the council's committee for the care of mental defectives he was actively concerned in setting up colonies for the mentally handicapped

He was born in Donegal in 1866 the son of Dr S Torrens Haslett of the Colonial Medical Service. He was educated at the Academical Institute Londonderry Trinity College Dublin and the London Hospital After qualifying in 1889 he held resident appointments at the Poplar Hospital and St. Luke's Hospital for the Insane and a clinical assistantship at the National Hospital for Paralysis and Epilepsy In 1892 he became proprietor and medical superintendent of Halliford House a private mental hospital at Sunbury-on Thames

Soon after he settled at Sunbury he was elected to the Staines board of guardians, the Middlesex insurance committee and the Sunbury urban council. All these interests were a preparation for his work on the county council *He was also a justice of the peace for Middlesex* He was created a knight in 1938 for his public services.

Sir William married in 1922 Norah daughter of Mr W. A. Macan She survives him with a son and three daughters.

## Appointments

ELLIOT, MARGARET M., M.B. Sheff.: school M.O., Sheffield.

GHOSH, A. K., M.B. Calcutta, D.OBST.: registrar in obstetrics and gynaecology, Peterborough Memorial Hospital

KELLY, J. F., M.B. N.U.I., D.P.H.: asst. M.O., British Railways (London Midland region)

MCGRATH, S. D., M.R.C.P.I., D.P.M.: resident medical director, St John of God Private Psychiatric Hospital, Stillorgan, co. Dublin.

MORGAN, J. D., M.B. Sheff., F.R.C.S.: consultant orthopaedic surgeon, Wingfield Morris Orthopaedic Hospital, and accident service of the United Oxford Hospitals

PAUL, JACK, M.B. Witwatersrand, D.C.H.: appointed factory doctor, Tottenham, Middlesex.

PORTER, K. R. D., M.B.E., M.R.C.S., D.P.H.: deputy senior administrative M.O., Oxford R.H.B.

PUGH, R. C. B., M.D. Lond.: whole-time clinical pathologist, St Peter's, St Paul's and St Philip's Hospitals, London.

WILLIAMS, J. H., M.B. Lond.: asst. M.O., British Railways (London Midland region).

South Western Regional Hospital Board:

EARLE, B. V., M.D. Dubl., M.R.C.P., D.P.M.: consultant psychiatrist, Exeter clinical area

MOORE, H. D., M.B. Sydney, F.R.C.S., F.R.C.S.E.: consultant surgeon, Exeter clinical area.

PAYNE, J. W., M.B. Manc., F.R.C.S., D.O.M.S.: consultant ophthalmologist, Plymouth clinical area.

Amended notice.

# Notes and News

## THERAPEUTIC SUBSTANCES

THE Therapeutic Substances Act, 1925, has been amended to include within its schedule parenteral preparations of oxytetracycline, and the Therapeutic Substances Regulations, 1952, have been amended to include methods of preparing this drug[1] Oxytetracycline is removed from the list of substances which may be sold only on the prescription of a doctor, dentist, or veterinary surgeon[2] More up to date regulations for insulin preparations are approved[1] Erythromycin, neomycin, oxytetracycline, polymyxins, cortisone, corticotrophin, and hydrocortisone are added to the substances controlled by the Penicillin Act, 1947[3] All these measures come into operation on Jan 1

## DISORDERS OF INFANCY

AT a meeting of the Devon and Exeter Medico Chirurgical Society on Dec 16, Dr F S W Brimblecombe spoke of some common disorders of childhood It is a sombre thought, he said, that if the human female had always carried out efficiently her natural function of lactation there would have been no problems of infant feeding, uncountable millions would not have died in infancy, and the whole history of the human race might have been changed It is only during the past half-century that we have had anything approaching an efficient substitute for breast-milk or hygienic methods of artificial feeding

Underfeeding is common, overfeeding very rare If a baby fails to thrive it is wise to seek the cause in the baby rather than in the feed A baby who screams on being fed should be examined for an anal fissure The word marasmus is now obsolescent Most of the causes of failure to thrive can now be recognised Wrong feeding is one, but a rare one Another is hiatus hernia, here the function of the cardiac sphincter is lost and the patient vomits from birth especially when laid flat The vomit contains mucus and sooner or later, owing to œsophageal ulceration, blood Painful swallowing from the same cause produces anorexia, and occult bleeding may give rise to anæmia The diagnosis is a clinical one, for confirmation by radiography is difficult Feeds should be thickened and the baby sat upright To free a stomach which has ridden up into the chest and become adherent surgery is occasionally required.

Bottle fed babies, apparently thriving, sometimes start to vomit at the third or fourth month, become costive, and develop unexplained pyrexias These infants need not die Necropsy reveals calcification in the proximal renal tubules This calcification is radiographically demonstrable during life In these cases, first described by Dr Reginald Lightwood, there is acidræmia with a urine constantly alkaline This disorder, persistent renal acidosis can be treated successfully with large doses of sodium bicarbonate In another group, clinically similar there is hypercalcæmia of unknown origin which is equally controllable by a calcium free diet

Infants are occasionally poisoned accidentally by the too liberal application of boric powder to raw buttocks Boric poisoning causes a generalised rash which desquamates, diarrhœa and vomiting, and perhaps coma and death Infants who suck or gnaw at their cots which have been painted with lead paint occasionally develop lead poisoning In infancy plumbism manifests itself in pallor, abdominal pain, drowsiness and convulsions Radiography shows a lead line round bones, but there is no polyneuritis and blood changes are absent Circumcision, which is responsible for sixteen deaths annually, is justified only in infants who cannot pass urine A tight prepuce—and tongue tie—are physiological states in infancy

## A NEW OUTPATIENT DEPARTMENT

BETWEEN 1935 and 1948, outpatient attendances at St James' Hospital Balham, rose from 30,000 to well over 100 000 annually, and the need for an enlarged outpatient department became urgent The new building, which is now in use, is a notable example of imaginative hospital planning The design s pleasing features include a large and beautifully furnished lounge for visitors or waiting patients, a pram store conveniently situated near the postnatal clinic and two automatically operated stretcher lifts, fitted with levelling devices All internal structures have been
to allow alterations to be made quickly and easily
transverse partitions may be removed and re-erected
where within a matter of minutes, and all cubicles
examination rooms have interchangeable electrical
To enable patients to find their way about, each depart
has its own colour scheme, and the hospital proposes t
appointment cards in corresponding colours Noise in c
is kept down by perforated "acoustic" boards in the c
and the floors are made of cork tiles Door handl
designed for elbow action All furnishing fabrics
pleasantly harmonious patterns, and particular att
has been paid to comfort and utility in designing the cons
room furniture The aim has been to evoke an atmo
at once sympathetic and quietly cheerful, as well as to p
for functional efficiency

categories

## A LIGHT SPRING CALLIPER

Mr G Douglas Nickels, M C S P, remedial gymn
Mount Vernon Hospital, Northwood, Middlesex,
The accompanying photograph shows a new light
calliper that has been used in the department of p
medicine at Mount Vernon Hospital for the last three
It has been developed primarily for the hemiplegic
but has been used successfully on other patients with
foot" The advantages of this type of calliper are

(1) Light weight It weighs about 9 oz
(2) Ease of fitting It can be fitted by the physiotherapist
department
(3) Low cost It costs about 15s

The calliper is made in three sizes to fit different size
It is $13\frac{1}{2}$ in long and measures $3\frac{1}{2}$–4 in under th
It is wound from 6 and 8 B I S gauge wire. The side
are joined at the top by a stiff leather band with str
buckle

[2] The Therapeutic Substances (Supply of Oxytetracycline for Agricultural Purposes) Regulations 1954
[3] Therapeutic Substances (Control of Sale and Supply) ulations 1954

[1] *Publ Hlth Rep Wash* 1954 69 1084

For fitting the heel of a good lace up walking shoe is illed to take a ¼ in steel peg This acts as the fulcrum, id makes a firm attachment for the spring Inversion can corrected by drilling the hole at an angle dependent on e degree of correction required The calliper is then sprung n to the projecting ends of the peg The calliper is not tended to be a 90% foot stop but it is a spring designed to lp the patient to lift his foot when walking

## THE SCALPEL, THE SWORD

This title has been given to an emotional biography of orman Bethune a Canadian surgeon[1] In 1927 he was ying of pulmonary tuberculosis in a famous New York anatorium There he read of a wonderful new cure for his isease—artificial pneumothorax. He demanded the treatment and was cured. Later he became a skilled thoracic urgeon, but he threw up his career on the outbreak of the panish civil war and went to Madrid to help the anti Fascist orces. When the war ended he returned to Canada and oined the Communist party But his turbulent spirit called or something more exciting than civilian practice: the hinese people were fighting against invasion and there was n urgent need for doctors Early in 1938 Bethune left ancouver for Hong Kong taking with him enough equipment nd supplies to fit up several surgical units He reported o Mao Tse-tung who welcomed the suggestion of a mobile perating unit close to the front Bethune seems to have lone remarkably good work under very difficult conditions ut towards the end of 1939 he contracted fatal septicæmia rom an infected operation wound This biography carries he recommendation of the Book Society and will probably e widely read. Doctors may not be wholly convinced by he publisher's claim that "No doctor not Hippocrates nor Jenner nor Pasteur nor Sir Alexander Fleming is known and enerated by as many people as Norman Bethune

## AUTOMATIC AMPOULE INJECTOR

This indefatigable Sir Christopher Wren somehow found ime in the midst of his more widely known pursuits, to nstruct one of the earliest practicable syringes. His iginal model[2] which he used experimentally on dogs, onsisted of a hollow quill attached to a bladder containing the uid for injection and in 1656 he wrote: I am in further ursuit of this experiment which I take to be of great concernent and which will give great delight to the theory and ractice of Physick. Three centuries have passed since en, and the technique of injection continues to evolve he latest of many refinements are incorporated in the evice known as the Ampin[3] which is an automatic mpoule injector for routine and emergency hypodermic jections. In America it was first demonstrated at the merican Medical Association convention at Chicago in 1948 t consists of an ampoule of the solution for injection, under ressure of an inert gas, connected by flexible transparent tub ng to a needle with a glass cover To make an injection the over is removed and the needle inserted into the selected ite with the usual antiseptic precautions. (If a vein is accidenally entered, blood will flow into the tubing when this is inched and released) The tip of the ampoule is then snapped y bending the transparent tubing and the pressure of the as forces the solution through the needle The whole rocess, it is claimed is considerably quicker than ordinary ethods of injection, and in addition it ensures accuracy of osage and maximum sterility Syringe transmitted hepatitis avoided since each ampin is used once only—which ncidentally means that patients have a sharp new needle for ach injection The possibility of glass fragments passing own the needle has been investigated and we understand hat the risk may be discounted The method is specially uitable for general practitioners, district nurses, and mid ives, and the ease of administration will be attractive to usy anaesthetists Intravenous infusions of saline and plasma an also be given in the same way

The British representatives say that the ampin is actually heaper to use than the traditional syringe Preliminary gures which they have obtained from hospitals with a central yringe service indicate an over-all cost including maintenance and renewal of about 9d. per injection One ampin, on the other hand can be bought by hospitals for rather less than 7½d; and the labour and expense of servicing are of course eliminated Both these figures are exclusive of the cost of the the drug

The manufacturers and distributors in this country are Curzon Gerrard & Co Ltd Fountain Lane Oldbury Birmingham.

## FILMS ON DENTAL EMERGENCIES

Most medical graduates are required to enter one of the three Services shortly after registration and sooner or later many of them—particularly those who join the Royal Navy—find themselves dealing unaided with dental emergencies For this reason the Admiralty has issued a series of colour films and film loops which show in detail the measures which may be used to tide patients over until they can be seen by a dentist

Three of the longer films describe dental inflammatory conditions, operative techniques (including local anæsthesia and the treatment of postoperative pain and bleeding) and the management of injuries to the teeth and jaws. Nine short film loops in colour have also been prepared each showing the extraction of a tooth. All illustrate clearly by means of diagrams models and practical demonstrations, the essentials of diagnosis and treatment of inflammatory and traumatic dental lesions. The commentaries are good the exposition is unhurried and important details are suitably emphasised.

These films were designed originally for Naval doctors, but the Admiralty suggests that they might also be helpful to senior medical students. The films will shortly be available for hire or purchase from the director of Naval training at the Admiralty

The Milne medal in tropical medicine has been awarded to Dr G P Lowther

### Royal Faculty of Physicians and Surgeons

At a meeting of the council on Dec 21 with Prof Stanley Graham, the president in the chair the following were admitted to the fellowship:

Jasoda Jiban Das, J A Rundle W C Watson

### Royal Society

Locke research fellowships have been awarded to

Dr M de Burgh Daly to work on carotid sinus reflexes and hæmodynamics of the pulmonary circulation, at University College London

Dr J C F Poole to work on the effects of fat absorption and blood coagulation and thrombosis, at the Sir William Dunn School of Pathology Oxford

## University of Sheffield

Mr O Daniel has been appointed senior lecturer in surgery, and Dr D Balducci research assistant in bacteriology and virus diseases

## University of Edinburgh

On Dec 17 the following degrees were conferred

*M D*—G S Kilpatrick * J W Lusk, † G M Maxwell
*Ph D (in the faculty of medicine)*—A. N George, Sourindra Mohan Ghosh I A Macpherson, D I Nisbet
*M B , Ch B*—A J Bennet A A H Brown, J A Brown, C F M Caird, P G Coffey, R W Davidson H P Davie G F Davis, P G Drummond Smith, W D Fanner Alan Ford Hunter, D A K Goldenhuys H C R Hinwood P Y Kyle M H Lea, Kian Poen Lim A G Mackinnon D G Mochie, Denis Moore * Sheila M L Moore, D R Oliver, W F Parrott, Shirley A Peacock, W H Rable, J L Smith, A. T Thomason, R A P Whitelaw, John Wood, I F Young

* In absentia † Highly commended

The following diplomas have been awarded

*D P H*—D F Baxter
*D M.R D*—W N Boyd, R F Cant, J H Greig A H Morris A A Wild
*D Psych*—J G Henderson, P J Zeck

The George Guthrie research fellowship in child health was awarded to Dr J F J Collins, and the Hastilow research scholarship in rheumatism was awarded to Dr W R M Alexander

## Royal College of Surgeons of Edinburgh

At a meeting of the college on Dec 15, with Prof Walter Mercer, the president, in the chair, the following were admitted to the fellowship

W A Baker, G T F Braddock, Guru Kripa Chaudhuri J N de Klerk, C J Dewhurst J B Doss, J M du Toit, Mourad Mahmoud El Fiki Harry Fine, W D Graham J J Ironside A J A McCormick, G T Mair K P P B Menon, M J Meter Durga Prasad Misra G F Murnaghan, Bhalchandra Vasudeo Nabar Jagdish Swarup Pathak, James Piggot, Nukalapati Balakrishna Reddy, W C Robinson Roy Shree Krishna, Pramod Karan Sethi, Gajendra Sinh R. G D Taylor

## Royal Sanitary Institute

Fellowships have been conferred on

Dr J C R. Buchanan Colonel P J L Capon Dr Archibald Dodd, and Dr William Hogg

## University of New Zealand

Mr H M Carey, who has been acting professor since Prof Spence Smyth resigned early this year, has been appointed to the postgraduate chair in obstetrics and gynæcology at Auckland University College The appointment carries also the medical directorship of the National Women s Hospital under the Auckland Hospital Board

Professor Carey was born in New Zealand and graduated M B at the University of Sydney in 1941, having held a part time lectureship in physiology and biochemistry After holding resident posts at the Royal Hospital for Women Sydney and Queen's Park Hospital, Blackburn Lancashire he spent four years as senior registrar in obstetrics and gynæcology at the Postgraduate Medical School of London. He also spent a year in the department of obstetrics at Johns Hopkins Hospital From 1943 to 1945 he served in the R.A A F as officer commanding No 1 Aviation Medicine Section He began work in New Zealand as assistant in the professorial unit early in 1954 He has published papers on the use of ion-exchange resins oxytocics and fœtal distress

## McGill University, Montreal

Dr W Clifford M Scott has been appointed associate professor in the department of psychiatry to organise facilities for training in psycho analysis

Dr Scott graduated from the University of Toronto in 1927 After working under Prof Adolf Meyer and Prof Macfie Campbell, he continued his studies in London at the National Hospital Queen Square and the Institute of Psycho analysis taking the D P M in 1934 He later became director of the Clinic of Psycho analysis in London and during the late war was a psychiatrist in the E M S He is a member of the staffs of the Institute of Psychiatry and of the Bethlem Royal and Maudsley Hospital London He is also an assistant editor of the *International Journal of Psycho-analysis* and president of the British Psycho Analytical Society

## E E G Society

A meeting of this society will be held at 10 30 A M on Saturday, Jan 8 at the National Hospital, Queen Square, London

## London County Medical Society

The annual dinner of this society will be held at the Talbot Restaurant 64, London Wall, E C 2, on Tuesday, Jan 18, at 7 30 P M , when Dr Robert Forbes secretary of the Medical Defence Union, will speak on medical litigation Tickets (11s 6d ) may be had from Dr A M Ramsay, Royal Free Lawn Road, N W 3

## Exhibition of Israeli Scientific Publications

This exhibition, which is being held at the Consulat Israel, 18, Manchester Square, London, W 1, is to open until Jan 7

## Association of Clinical Biochemists

*Southern Region*—The annual general meeting of region is to be held at University College Hospital, Lon W C 1, on Monday, Jan 10, at 3 15 P.M At 4.30 scientific papers will be read

## Institute of Diseases of the Chest, London

Clinical demonstrations on chest disease are given Fridays at 5 P M at this institute (in the grounds of Brompton Hospital, Fulham Road, S W 3) They are without fee to doctors The next series will begin on Ja and end on April 1

## Colonial Work of the N A P T

The National Association for the Prevention of Tubercul has presented to the secretary of State a memorandum on association's activities in Colonial territories Over the nine years this association's work in backward areas h included large scale health propaganda, and the provi of well trained professional teams By means of N.A. scholarships, 55 doctors, nurses, and sanitary workers, fr 18 Colonies, have been enabled to come to Britain for stud The memorandum drew attention to the Colonies' need more tuberculosis specialists and greater research faciliti and indicated the association's willingness to assist t Colonial Office in overcoming the pressing problem of losis among immigrants to Britain from the Colonies.

---

CORRIGENDUM *Scottish Appointment*—Dr C J Swan is chairman of the General Medical Services Subcommit (Scotland), and *not* of the Scottish Health Services C as we incorrectly stated last week (p 1336) Captain J Younger is chairman of the council

---

Sir Lionel Whitby is to be visiting professor of medicine a New York State University College of Medicine in January

*The Wellcome Historical Medical Museum* has moved f Portman Square, London W 1, to the Wellcome Research In tion, 183 Euston Road, N W 1 Exhibitions dealing with pri medicine and with child welfare through the ages are open to public in the new premises (Monday to Friday, 10–5)

# Diary of the Week

# MAN AS AN EXPERIMENTAL ANIMAL*

Sir GEOFFREY JEFFERSON
C B E M.S Lond. LL.D., F.R C S F R.C.P F.R.S
ERITUS PROFESSOR OF NEUROSURGERY IN THE UNIVERSITY
OF MANCHESTER

THERE are some branches of research in which man the pre-eminently suitable in fact the only possible bject All have to do with the nervous system and pecially those concerned with sensation with pain and ith thinking

### Experiments on the Brain

The first operation for a brain tumour was performed n Nov 25 1884, and gave rise to discussions in the imes

Someone signing himself F R S' led off on Dec 16 ith a long letter describing in vivid terms what had appened It seemed to him to be a wonderful oppor unity for a telling reply to the Bishop of Oxford and ohn Ruskin who had just spoken strongly against hat was so curiously called vivisection The point bout the famous operation was that the situation of e tumour had been localised to the upper part of the otor area by a comparison between on the one hand e patient s symptoms and signs, and on the other hand e maps of cortical localisation which resulted from the nimal experimentation of the Germans, Fritsch and litzig and more still, of David Ferrier ' F R S., ad a picturesque literary style which you can savour rom the following extract from a very long letter escriptive of the steps of the logical application of perimentally verified facts

> ' While the Bishop of Oxford and Professor Ruskin were somewhat intangible grounds denouncing vivisection at xford last Tuesday afternoon there sat at a window of the spital for Epilepsy and Paralysis in Regent s Park in an valid chair propped up with pillows, pale and careworn t with a hopeful smile on his face a man who could have oken a really pertinent word upon the subject and told the ht Rev prelate and great art critic that he owed his life d his wife and children their rescue from bereavement and y to some of these experiments on living animals which so soundly condemned.

e Bishop of Oxford replied on Dec 19 that if a ct knowledge of the secrets of the human frame is ed in the interests of mankind let mankind be the ns These letters led to a shower of further letters, n Christmas Day mostly in support of F R S R S had to add a further note on Dec 26 saying the poor man was dead (of infection) In a long r on Dec 27 the *Times* took the view that in spite e eventual fatality Rickman Godlee s experimental tion had been fully justified and that the gateway erebral surgery had been opened This was an rtant pronouncement and true Do I need to add on Dec 26 there was a letter from James Whitson tant surgeon to the Glasgow Royal Infirmary saying this was not the first operation on the brain for our, that a Scotsman William Macewen had got first ? Whitson was quite correct. Then letters to vie for place with news of Mr Gladstone s 75th day letters on The state of the business at nisi s and scandalised objections to some undraped es in Alfred Steven s designs for the decorations of dome of St Paul s—designs that had the weighty mendation of Sir Frederick (later Lord) Leighton Mr (later Sir) E J Poynter—men whose artistic g was nearly as high then as that of Velasquez Raphael

So we see that remarkable experiment come and go to lead to more in the fullness of time than *The Lancet* had lugubriously prophesied for it in its leader on Nov 10, 1883 *The Lancet* held that *acceptance of the* laboratory discoveries was not unanimous and that the facts themselves were somewhat confusing (as indeed they were) The leader proceeded

> But it must be confessed that the aid localisation has afforded to treatment has been small and practically confined to cases of surgical interference Even of these cases there are very few—scarcely more than could be counted on the fingers on one hand—in which the power of localising cerebral disease can be said to have been the means of saving a life that would have been lost without it

It concluded with these minatory words

> If Dr Ferrier s suggestions meet with much practical response it is to be feared that cerebral localisation will soon have more deaths to answer for than lives to boast of

These lines were evidently written either by a physician or a pessimist, the author could of course have been both

We see, then that these experiments on man had the mixed reception that we should have expected at that date It required the courage of a man like Sir Victor Horsley and after him Harvey Cushing to silence opposition and to win the confidence of the world.

All operations are of their nature experimental the statistical results are broadly known and from them the general impersonal risks can be calculated In some what concerns us most is danger to life itself in others fatality can be almost excluded and the experimental side depends on the success that can be expected, the relief that can be anticipated in the individual instances No statistics have so personal a message If it comes to that all medical treatment is also experimental As Professor Pickering has pointed out, the prescription even of rest in bed for two or three weeks or of a bottle of cough mixture, are experiments the results of which deserve closer observation and quantitative analysis than they got.

### Sensation

I mentioned just now that man was the only suitable animal for experiments on sensation and on pain It was by regarding closely the stages of sensory and motor recovery after nerve suture that what we call generally sensation was broken down into a number of components (light touch the recognition of pain pressure temperature localisation of the point touched and so forth) It seemed to Henry Head who was deeply *interested in this subject that he would appreciate the* whole thing better if he had some nerves cut in his own left arm This was done by Dean and Sherren of the London Hospital in 1904 Head chose what he thought were purely cutaneous nerves and came to some wrong conclusions by that mistake as J S B Stopford pointed out His other mistakes in interpretation have been pilloried by F M R Walshe The correctness or otherwise of Head's results is beside the present point, which is that he decided to turn himself into his own experimental animal Wilfred Trotter and Morriston Davies followed suit shortly afterwards and arrived at conclusions that have stood much better the test of time Since then the personal experiment has been applied by other research workers.

#### THE PAIN OF CANCER

A constant problem for the neurosurgeon is the pain of malignant invasion of the skeletal tissues in various forms especially in cancer of the uterus and prostate How to help these sufferers to whom peace cannot sufficiently be brought by morphine ? Foerster in Breslau divided the posterior or sensory roots or the spinal nerves without giving much relief to patients with pain of any

---

rt of the Stephen Paget lecture delivered before the Research Defence Society on Nov 4 1954 Published by courtesy of the Editor of *Conquest* the society s journal in whose January issue the lecture appears in full origin—relief, that is, commensurate with the disadvantages of denervating large areas of skin and muscle As a by-product Foerster was able to plot the nerve-supply of the different dermatomes of man in as definitive a way as is possible with something a trifle individually variable By stimulating the distal ends of the nerves he showed for the first time the vasodilatation of the vessels of the skin of the relevant spinal segment One has the feeling in reading his reports (as one had in conversation with him) that Foerster was basically an experimental physiologist rather than a therapeutist and that he chose his cases sometimes with a view to filling in a missing space in his collection of fact

A much better piece of physiology was already on the way when Foerster was doing these operations—the operation of cordotomy However Foerster had had a part in that as well, having persuaded Tietze to do and successfully, this operation

A fortunate chance fell to Spiller in Philadelphia, who observed that a coloured patient in his hospital was numb to pain and temperature up to a level on his trunk, without paralysis The sense of touch and pressure was retained This patient had tuberculosis and shortly died At the post-mortem two very small tuberculous nodules were found symmetrically placed in the spinal cord in the situation of the spinothalamic tracts There had been other suggestive evidence, notably that of Türck of Vienna, suggesting that these fibres were responsible for the transmission of pain Spiller at once saw the possibility of turning the misfortune of his patient to the good of others He persuaded a surgeon, Martin, to divide this part of the spinal cord in another person with unbearable pain The result was so great a success that the operation has since become a standard one

The optimum sites of the partial spinal sections have been worked out in recent years with great diligence by J C White of Boston, plotting the effect of limited sections of the cord under local anæsthesia No approach to the operation which is not of an experimental nature is likely to be long successful More recently still Talairach and David in Paris have tried the effects of destruction of the chief nuclei for the reception of pain in the brain itself by destroying them by electrocoagulation These are essentially human experiments of a high order and involve the use of the Horsley Clark stereotactic apparatus to which we shall shortly come back

Experimental vertical sections of the human spinal cord to relieve pain in the upper limbs were made by Donald Armour in London and Tracy Putnam in New York They have been used by the French for pelvic cancers also But these, though highly experimental in the case of man, were no more than applications of some animal experiments by Brown Séquard long ago, experiments that led Brown-Séquard to some quite wrong conclusions about sensation, since he equated "sensation" with "pain" and little else

VISCERAL PAIN

Other revelatory experiments on pain in man are those on visceral pain Such were the old observations of Lennander that crushing and burning the intestine and gall-bladder were quite painless, whereas traction on the mesentery was not John Morley investigated the agonising shoulder tip pain experienced by some patients with general peritonitis or chemical peritoneal inflammation such as follows the perforation of a gastric or duodenal ulcer He scrubbed the under surfaces of the diaphragm with gauze and abolished the referred pain by experimental procaine block of the nerves supplying the shoulder-tip area

[illegible] the same line were the experiments pursued by [illegible] others of having patients or medical students swallow inflatable bags F H Bentley and Smit using that technique, showed that the pain of duod distension was abolished by section of the spl nerves The result of important researches by se investigators was to show that distension and trac were the chief causes of visceral pain, the peri reference of which had been so acutely observed at bedside by James Mackenzie of Burnley fifty years and more cogently by Sir Thomas Lewis

No-one indeed worked with more whole heartedn in observation on the character and reference of p in human beings than Sir Thomas Lewis—the detr as it were of "clinical science," a term invented Stephen Paget's father He accepted no interpreta of symptoms that he could not experimentally verif the living subject This one sentence gives no idea the years he spent on painstaking work, and his obser tions on the pains of angina pectoris and of other visc and limb pains are classical No less were those of J Kellgren who explored the pains arising in musc fasciæ, and the ligaments of joints by injecting amounts of hypertonic saline into these structures observing the site, often at a distance, of the sev but temporary pain that followed He has told he had some 1000 painful injections of one sort or anot to find their effect Usually Kellgren was his own Lewis's test animal None of this work could have done on animals since the whole point was the descripti of the character of the pain, its situation in relation the position of the causal agent and its relation to nature of the stimulus

HEADACHE

No better example of experiment on man co found than in the investigation into the caus headache by the planned production of pain in the l Notable researches have been those of G W Pick D W C Northfield, and H G Wolff and Bronson and other collaborators, though many besides have ad their quotas

These all confirmed the ancient observation that brain itself is quite insensitive, but they added someth new It was that the stimulation of the cerebral bl vessels and some of the brain's coverings by direct indirect means led to referred pain somewhere on head's surface but according to the site of the stimulat It was shown that the violent but short-lived head that follows histamine injection is accompanied dilatation of the cerebral vessels and by a pronou increase in the amplitude of their pulsations It further shown by Pickering and Hess that their intensity of the headache corresponded with the of pulsation, being most severe when pulsation greatest

This relation between a sort of slackness of the cer vascular system and headache was confirmed by an series of observations that had results that were sur to many It was demonstrated that the surest w give a person a headache was to lower the intrac pressure by draining off cerebrospinal fluid On contrary, raising the pressure by lumbar injecti saline into a normal person, even to five times and the normal, as I have done myself, does not headache Evidently, then, the headache of a tumour or abscess or blood clot is not due to pressure alone, for some pressures experimen reached were far above those registered by most tumours

It is generally agreed that tumour headache is ca by distortion of normal intracranial relationship due either to traction on dural septa or to drag on and on the sensory cranial nerves, of which, of the trigeminal has the widest supply Some of human experiments were daring, such as those of d Wolff who introduced inflatable rubber balloons into o third and into the lateral ventricles of conscious tients and charted the sites of their induced headaches

The common headache of mankind, migraine and ondo migraine is due to dilatation of the vessels in e scalp, bone and dura mater In these cases the rebrospinal fluid pressure is never high and most lief can be obtained by the use of vasoconstrictors of e ergotamine group which it has been shown have ore effect on the extracranial arteries than on those side the dura I cannot here discuss more widely this mmonest of the pains to which mankind is heir But ough has been said to make plain how much these orkers have done to clarify a subject that was full of nfusion and of conjecture until experimental recourse as made to the right animal—man himself

### Stimulation of the Cerebral Cortex

Present-day views on epilepsy have been derived almost tirely from experiments on man The great protagonists ave been first Victor Horsley and then Ottfrid Foerster nd Krause who got only so far Much more fruitfully ave worked Wilder Penfield and Herbert Jasper and eir co-workers in the Montreal Neurological Institute

The new observations take origin not only from lectrical stimulation of the surface of the brain—even f its less exposed parts—in conscious patients but also rom direct recordings of electric potentials from the xposed brain surface in the search for damaged areas uch as could be regarded as the discharging lesions’ in Hughlings Jackson's phrase) or their synonym epileptogenic foci The discovery and excision of hese areas has led to many cures

Cortical stimulation to map out the site of the motor rea is now a commonplace of neurosurgery and has een employed by myself and by too long a list of eurosurgeons for them to be named It was early used y Victor Horsley as he reported in 1888 and again in 900 to mark out the exact piece of brain that needed moval in focal epileptic attacks or the wild involuntary ovements of a man's arm That was a straightforward iece of physiology—the application of Ferrier's work ad the much more acute observations of Sherrington hich had, to be sure, not yet seen its final fruition ith the anthropoids

More exciting were the two cases published in 1900 by arvey Cushing on sensations resulting from stimulations the post-Rolandic area in man Operating under cal anaesthesia he established the sensory function of e human postcentral strip Penfield since that day rty six years ago has greatly extended these observa ons on both the motor and sensory and other responsive eas of the brain His maps of the excitable cortex ill eventually it is to be hoped supplant those of the t and monkey so much more beloved of physiologists ecause they have been their laboratory familiars

Ferrier many years ago said that all parts of the cortex ould prove to be excitable but he could not demonstrate citability himself except from restricted areas of the ain the greater part was unresponsive Ferrier's ophecy was long unfulfilled and only recently has me closer to confirmation Thus we now know that sponses must be looked for not only in movements of *e limbs or in sensations or in flashes of light or sounds* odours but in two other directions The first is in the tonomic or visceral changes that may be the replies stimulation of some areas (changes in heart rate spiration rate blood pressure intestinal movements, c ) This work has mainly been done on animals he second and much the more exciting even dramatic scovery was made by Penfield—that stimulations of e temporal lobe in human beings may evoke experiences ctures in the mind An example may be given of the sponse of a woman of 32 who had epileptic fits of a minor sort. Each remark corresponds to a separate stimulus

> I hear singing Yes it is White Christmas
> " There is an orchestra too yes a choir That is different
> a voice—talking—a man ' Yes, I have heard it before
> a man's voice talking Yes about the same as before
> There is that sound again—like a radio programme—a man talking She said that it was a play

Results of a similar kind or the evocation of a familiar scene a moment or two only in life well accepted by the patient, in no way frightening but all with a considerable content and depth of experience have been obtained from other cases But it is by no means anybody's brain that will yield such vivid experiences confirmatory results by others must still be made Something very like that can occur spontaneously in patients with temporal lobe tumours

The upshot of this and other work is that a seizure *pattern has emerged recognisable as coming from one* or other temporal lobe It is very much to the point that these seizures, previously labelled psychomotor fits are often caused by extensive scars from damage perhaps at birth The excision of the scar and of anterior parts of the pathological temporal lobe has led to the cessation or great diminution in the frequency and severity of the attacks in a proportion claimed to be as high as 2 out of 3 cases Murray Falconer has now had some success in improving not only the fits but the behaviour of delinquent children and young adults subject to this kind of seizure Experiments carried out on man in the laudable attempt to relieve him of epilepsy has in many ways helped greatly in our interpretation of the brain's integration and of its mechanisms It marks a major advance in man's understanding of himself

The advance has been assisted by the explorations of frontal lobe physiology Our new knowledge has come about from again two sources—first major excisions of the frontal lobes of which I myself reported the first 8 European examples in 1937 and again 75 examples in 1942 Going still further Krynauw in Johannesburg reported in 1950 the first cases of removal of a cerebral hemisphere from children already hemiplegic and suffering from fits that started in the paralysed limbs It was found that the mental state of these children was often improved by the loss of half of the brain's cortex the remaining healthy half being no longer disturbed by the flow of disturbing impulses from the abnormal parts. *This was much the same conclusion as I had* reached myself from the lobectomies for brain tumour Close on the heels of that came the rising popularity of prefrontal lobotomy and its modifications for mental disorders which we owed to the inspiration of Egas Moniz (1936) All this is very much in the field of human experiment Equally experimental in their way were the introduction of the malarial treatment of general paralysis (Wagner-Jauregg 1917) and the insulin (Sakel 1927) metrazol (Meduna 1937) and electric shock therapy (Carletti and Kalinowsky 1937) of the psychoses

### Conclusion

Plainly it would be unthinkable that man should be used widely in experiment on the propagation of danger*ous infections It seems indeed that he is only suitable* as a test subject to those affections or diseases to which he alone is subject or in which his subjective responses to experiment are essential to the experiment itself This is most true of the nervous system and already his acceptance of himself in this experimental role has led to the illumination of many a dark corner I am convinced that no surgeon is quite as con cious of the truly experimental nature of his work and of the opportunities it affords for physiological observations as the neurosurgeon

# PLASMA-17-HYDROXYCORTICOSTEROIDS IN PREGNANCY

R I S BAYLISS
M.A., M.D Camb, M R C P
ASSISTANT PHYSICIAN, WESTMINSTER HOSPITAL

J C McC BROWNE
F R C S, F R C O G
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY IN THE UNIVERSITY OF LONDON

BRENDA P ROUND
B Sc Lond
RESEARCH ASSISTANT

A W STEINBECK*
M D Sydney, M R C P
LECTURER IN MEDICINE, UNIVERSITY OF QUEENSLAND

*From the Departments of Medicine and Obstetrics, Hammersmith Hospital, London*

EVIDENCE suggests that during pregnancy the activity of the adrenal cortex is increased The adrenal glands of women dying at or soon after delivery weigh more and have a larger cortex than those of non-pregnant women (*Aschoff 1910, Aschner 1912, Huggett 1950*) The urinary excretion of certain adrenocortical steroids ("glucocorticoids," "11-oxysteroids"), measured by biological and chemical methods, is increased during pregnancy (Venning 1946, Tobian 1949, Cope et al 1951) Thus, using a bio assay procedure, Venning (1946) found increased excretion of glycogenic steroids during the first trimester of pregnancy and a further increase during the subsequent months In some instances there appeared to be a reduction in the amount excreted during the last month of pregnancy, and normal values were found shortly after delivery None of the methods used gave a true estimate of the total amount of adrenocortical steroids excreted in urine, because of difficulties in hydrolysing the conjugates present (Bayliss 1952, and Hurlock 1954)

In contrast with this evidence suggesting that amounts of adrenocortical C-21 steroids are elaborat pregnancy, no increase in the excretion of androgen 17-ketosteroids has been observed by Dingemanse (1937), Hain (1939), Pearlman and Pincus (19 Venning (1946), and Jailer (1951) Although Ve (1946) found no increase in 17-ketosteroids when ured by the Pincus antimony-trichloride method, is specific for saturated 17-ketones, there was an appa increase when measured by the Zimmerman react which determines both 17-ketones and 20 ketones, latter being metabolites of progesterone, which is to be formed in increased amounts during The most complete study of the excretion of 17-k steroids in pregnancy has been made by Huis in't (1954), who found with the Zimmerman reaction the excretion of total neutral 17 ketosteroids is sli increased during pregnancy, being somewhat more the first and third trimesters than during the s Much of the increase during the third trimester was to pregnanolones and to 11-keto-etiocholanolone *11 hydroxyandrosterone—compounds believed to* metabolites of C-21 adrenocortical steroids

While the present investigation was in Gemzell (1953) reported his findings on the plasma of 17-hydroxycorticosteroids in normal pre during the last trimester the concentration was four the normal level, and very high values were immediately post partum, but the concentration returned to the normal range six days after deli No conclusion about the variation in individual resp could be drawn, because the samples of blood were from different women at different times in their nancy In the present investigation the plasma hydroxycorticosteroids were studied in the same at about monthly *intervals throughout pregnancy* during the puerperal period.

---

* Thompson Scholar, Royal College of Physicians, London

TABLE I—LEVELS OF 17-HYDROXYCORTICOSTEROIDS IN PLASMA IN PREGNANCY

| Case no | Age (yr) | No previous deliveries | 17 Hydroxycorticosteroids (µg per 100 ml) | | | | | | | | | | | | | | |

—Mean level (and standard deviation) of 17-hydroxycorticosteroids plasma at each month of pregnancy and during puerperium in lthy women.

## Material and Methods

lirty eight women attending the antenatal clinic for first time in their present pregnancy were chosen at lom Eight subsequently developed complications iding toxæmia anæmia and hypertension, and have excluded from this report Of the remaining thirty underwent a normal pregnancy twenty nine were rered spontaneously and one had a cæsarean section use of a contracted pelvis Eighteen had borne lren before (table I)

imples of blood were taken at the first attendance thereafter at monthly intervals all these ante um samples being collected at about the same time ne afternoon In fifteen instances blood was collected n the umbilical cord at the time of delivery and further ples were taken from the mothers at various intervals eafter

he concentration of 17 hydroxycorticosteroids in the ma was estimated by a modification of the method Nelson and Samuels (1952) described by Bayliss and nbeck (1953) Compounds measured by this technique ude cortisone, cortisol (hydrocortisone) and their dro and tetrahydro metabolic reduction products mean plasma value for healthy women is 9 5 µg 100 ml with 95% fiducial limits of 3–16 µg per 100 ml

## Results

he results are shown in table I the month of pregnancy ng calculated from the time of delivery and the mean ls of 17 hydroxycorticosteroids in the plasma of the ty women at each month of pregnancy are shown in 1 At the third month the level of 10 µg per 100 ml he same as the mean value for non pregnant women reafter the level rises steadily the highest level ched being 24 µg per 100 ml during the last month gestation At the time of delivery the level in the bilical-cord blood was slightly higher than during the month of pregnancy Post partum the level in the ternal blood was high for twenty four hours and then urned gradually to a normal level by the eighth

The individual patients however showed considerable ation from the mean values In all of them the level 17 hydroxycorticosteroids in the plasma rose but in ne (cases 1–13) it rose higher than 20 µg per 100 ml some time during pregnancy, whereas in others ses 14–25) it rose to only 21–28 µg per 100 ml. and three (cases 28–30) it did not exceed 20 µg per 100 ml strative examples from each of these three arbitrary ups are shown in fig 2 No clinical differences were noted between the patients with the high and with the lower levels

In most instances the levels during the third and fourth months were within the normal range for non pregnant women, but high values were found in some at this time About half the patients had abnormally high levels by the fifth month and others, although not having abnormally high levels showed an increase above the values observed during the previous two months During the last month of pregnancy there was in most instances a further increase or no significant change compared with the levels in the eighth and ninth months, but in seven patients a definite fall took place at this time (cases 3 11 12 21 23 28 and 29)

Although the mean values for the cord blood and mother s blood in the last month of pregnancy were not significantly different in eight cases the cord blood had a higher level in five a lower and in two there was no significant difference

During the postpartum period there were considerable individual differences in the plasma steroid levels. Most of the patients had abnormally high values for the first forty eight hours after delivery Two had raised levels after this time one (case 14) on the third day and the other (case 18) on the fifth day Case 4 who had unusually high levels at the third month of pregnancy, also had a high level on the eighth postpartum day she was particularly anxious, and the high levels may have been related to emotional disturbances

No correlation was found between the height of the 17 hydroxycorticosteroid level during pregnancy and the weight of the placenta or of the baby at birth

## Discussion

These results show that in pregnancy the level of 17 hydroxycorticosteroids in the plasma is raised, in some cases to levels exceeding those found in patients with Cushing s syndrome (Perkoff et al. 1954 Bayliss and Steinbeck unpublished)

At least two problems remain unanswered what is the nature of the material which is present in increased amounts, and what is its origin ?

### *Nature of Material*

The chemical method used for the estimation of 17 hydroxycorticosteroids is relatively specific for 17 : 21 dihydroxy 20-ketosteroids such as cortisone cortisol and their dihydro- and tetrahydro derivatives We have found that in healthy non pregnant women the plasma

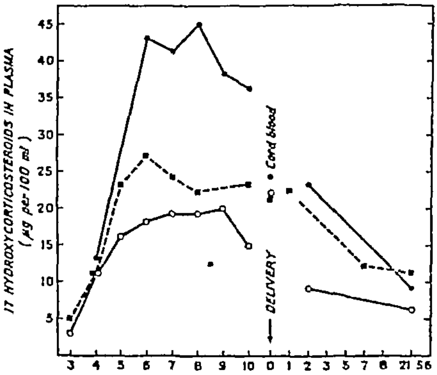

Fig 2—Three examples of the individual variation of 17-hydroxycorticosteroids in plasma during pregnancy

17-hydroxycorticosteroid levels are a measure of the amount of cortisol and also more polar derivatives—e g , tetrahydrocortisone Without further chemical analysis it is impossible to say what is the exact nature of the material measured in the plasma of pregnant women, but by paper chromatography Bush (1953) has found increased amounts of cortisol in the blood of such patients

*Origin of Increased 17-Hydroxycorticosteroids*

If the site of origin were either the fœtus or the placenta, the steroid levels in the mother would be expected to fall more rapidly after delivery than they do For example, after a single dose of cortisol acetate 200 mg by mouth the plasma level of 17-hydroxycorticosteroids falls from a maximum of more than 100 µg per 100 ml to normal levels within eight hours (Nelson et al 1952) In newborn infants the urinary excretion of 17 ketosteroids, glycogenic corticoids, and reducing steroids, and the plasma level of 17-hydroxycorticosteroids are low (Talbot et al 1943, Day 1948, Venning et al 1949, Klein et al 1954) Since Klein et al (1954) have found low 17-hydroxycorticosteroid levels in the blood of newborn infants but, like us, high levels in most samples of umbilical cord blood, it seems reasonable to deduce that the high level in the cord blood results from the high concentration in the maternal circulation, and that the hormones pass readily across the placental barrier Although small amounts of adrenocortical hormones have been found in placental extracts, it is impossible to tell whether these were produced in the placenta or are present in the blood retained there (Johnson and Haines 1952, de Courcy et al 1952) That some adrenocortical like steroid material is formed in the placenta is suggested by observations made on patients with Addison's disease who have become pregnant The excretion of 17-ketosteroids in two women with this disease has been studied during three pregnancies by Samuels et al (1943), Knowlton et al (1949), and Jailer and Knowlton (1950) In all three instances the amount excreted increased and in the last trimester reached normal levels In one patient the 17-ketosteroids were estimated by the Zimmerman reaction, and in the other by the same method during the first pregnancy and by the antimony-trichloride reaction in the second During the later part of the second pregnancy increased amounts of neutral reducing lipids were found in the urine and after delivery the excretion returned to abnormally low addisonian levels

TABLE II—LEVELS OF 17 HYDROXYCORTICOSTEROIDS IN PLASMA AT CÆSAREAN SECTION

| Case no | 17 Hydroxycorticosteroids (µg per 100 ml ) | |
|---|---|---|
| | Antecubital vein | Placental sinus and uterine blood |
| 31 | 55 | 45 |
| 32 | 46 | 48 |
| 33 | 35 | 19 |
| 34 | 50 | 42<br>42* |

* Specimen obtained from an anterior uterine vein before uterus was opened

Further evidence about whether the material is formed in the maternal adrenal glands or the placenta was sought by taking samples of blood simultaneously at cæsarean section from an antecubital vein and a placental sinus The results, shown in table II, are inconclusive because the steroid level was much the same in samples from both sites, and significantly the level in placental sinus blood was not higher than in the general circulation

It seems probable that the main site of origin of the 17 hydroxycorticosteroid material in pregnancy is the maternal adrenal glands because the glands are hypertrophied and during the puerperium the steroid level falls gradually The corticotrophic hormone responsible this increased adrenal activity could come from eith maternal pituitary or the placenta, which is known produce trophic hormones such as gonadotrophins, there is some experimental evidence that a hormone corticotrophic like activity can be extracted from placenta (Jailer and Knowlton 1950, Opsahl and L 1951, Tarantino 1951, Cohen and Kleinberg 195

Increased formation of 17 hydroxycorticostero pregnancy may explain why some patients with rh toid arthritis have a clinical remission at this time why diabetics may require increased amounts of in during pregnancy

## Summary

The plasma level of 17-hydroxycorticosteroids has b followed at about monthly intervals through the nor pregnancy of thirty women At delivery samples blood were taken from the umbilical cord, and therea from the mother at various intervals in the postpa period

The level of 17-hydroxycorticosteroids in the pl rose progressively during pregnancy, becoming in s patients very high After delivery the level fell, re to normal after a week

The nature and origin of the material formed pregnancy are discussed

We are grateful to Miss J Pirkis for her constant cons tious technical assistance, and to the nurses of the antena clinic and obstetric wards for their coöperation *This* w was supported in part by a Lund grant from the *Dia* Association

REGISTRAR

EUROLOGICAL UNIT WHITTINGTON HOSPITAL LONDON

IN tuberculous meningitis exudate may cause vascular clusions and fibrosis leading to cranial nerve palsies, yelitis hydrocephalus and spinal block Any manœuvre welcome which lessens the incidence of these complica ons and shortens the stay in hospital

Hitherto efforts to combat local obstruction produced y tuberculous exudate have been restricted to the troduction of purified protein derivative of tuberculin eparin streptokinase, and even trypsin into the cerebro oinal fluid (C S F ) after the obstruction has developed uch measures have in the main been hazardous and isappointing in their results

To prevent the formation of tuberculous exudate eemed more rational than to try and remove it after had been formed Because of its known property of iscouraging local tissue reaction we tried cortisone om the very beginning of treatment adding it to our stablished routine of intramuscular and intrathecal reptomycin and oral isoniazid Although alive to the heoretical dangers of giving cortisone to patients with uberculosis we were further encouraged to take this tep when we became aware of the fact that isoniazid, dmittedly a highly effective antituberculous agent seemed to cause tuberculous lesions to become initially nore vascular and swollen (Ritchie et al 1953 Dick 954) than either *p* aminosalicylic acid (P A S ) or strepto mycin This fact though not of great importance in ulmonary or renal tuberculosis, could be responsible or precipitating hydrocephalus or spinal block in patients vith tuberculous meningitis The simultaneous adminis ration of cortisone with the antibiotics might minimise hese changes in the tuberculous lesions and thus prevent bstructions

## Material

This report concerns twelve patients all adults with uberculous meningitis who were treated in the neuro ogical unit of the Whittington Hospital All were given ntramuscular and intrathecal streptomycin together with oral isoniazid, half of them were also given cortisone rom the beginning of treatment. Although not formally ontrolled the group receiving cortisone is comparable with that treated conservatively These numbers are oo small and the follow up period is too short for efinite conclusions to be drawn but the results are suffi iently encouraging to justify a preliminary publication.

## Method

Our routine was to give intramuscular streptomycin 1 g and oral isoniazid 400 mg daily *for six months, and* ntrathecal streptomycin 50 mg daily for from three to ive months No single criterion such as the C.S F ugar level is an adequate guide to when it is safe to stop he intrathecal streptomycin We have taken the patient s eneral condition shown by his weight temperature and rythrocyte sedimentation rate (E.S R.) together with he C.S F findings (rising level of sugar—preferably bove 40 mg per 100 ml —and falling cell-count) nto consideration We stopped giving intrathecal treptomycin when all these factors had been favourable or a month This routine was unnecessarily conservative Shane and Riley 1953 Lorber 1954), but all twelve atients were judged by the same standards

## Results

### Standard Treatment

The first six consecutive cases in this series were given the standard treatment Two were classified as early cases (Medical Research Council 1948) and four as intermediate

CASE 1 had a left hemiparesis on admission her physical signs were unaltered when she was discharged

CASE 2 developed bilateral optic atrophy becoming blind only after she had clinically recovered from the meningitis.

CASE 3 developed spinal block and blindness, went steadily downhill and died in three months At necropsy a great deal of thick exudate was found round the spinal cord and the base of the brain. His infecting organism was fully sensitive to streptomycin isoniazid and P A.S in vitro He was given some cortisone but only after the development of his complications when he was moribund

CASE 4 developed no neurological sequelæ but during the course of her miliary and meningeal tuberculosis she had severe hypoplasia of her bone-marrow with anæmia and leucopenia necessitating frequent blood transfusions. Her spleen was enlarged and soft at this time Under treatment her blood picture gradually became normal and her spleen impalpable but some months after her discharge from hos pital she developed hypersplenic pancytopenia her bone marrow was hyperplastic her spleen enlarged and firm and her peripheral blood poor in all the formed elements Splenectomy was followed by complete remission

CASE 5 developed a spinal block and required daily cisternal puncture for six months during the third month she became deaf

CASE 6 recovered uneventfully

### Standard Treatment plus Cortisone

The next six patients to be admitted were given corti sone from the outset in addition to the usual antibiotic therapy Cortisone was given to them as follows: 300 mg in divided doses on the first day 200 mg on the second and 100 mg on the third and every subsequent day until the intrathecal streptomycin was stopped To prevent suprarenal exhaustion the cortisone was then tailed off and covered by a short course of corticotrophin for twelve days thus

First three days cortisone 25 mg and corticotrophin 10 units

Second three days cortisone 12 5 mg and corticotrophin 20 units

Third three days corticotrophin 20 units but no cortisone

Fourth three days corticotrophin 10 units but no cortisone

All the patients on cortisone were given potassium chloride 3 g daily by mouth Serum-electrolytes were examined weekly

Of this second group of six cases one was classified as early and five as intermediate

CASE 7 had a left sixth nerve palsy and extensor plantar responses on admission

CASE 9 was stuporose and incontinent and had extensor plantar responses

CASE 10 had cerebellar signs and extensor plantar responses as did CASE 11 and CASE 12 both of whom were very dis oriented All these patients made rapid and uneventful recoveries as did case 8

CASE 8.—In addition to miliary tuberculosis and tuber culous meningitis this patient had several enlarged glands in his neck. These were thought to be tuberculous but were not considered to be a contra indication to the use of cortisone A month after the onset of treatment the glands broke down and had to be curetted The patient felt remarkably well throughout this and his meningitis cleared up without complication

## Discussion

As Brooks et al (1954) observe in tuberculous meningitis antibiotics have only a restricted effect if the circulation of the C.S F is interfered with as in spinal block They conclude that an agent must be found which can rapidly disperse fibrin and they say

> It is also clear that early prophylactic use of such an agent would be more effective than its therapeutic use under conditions of established or incipient block

Though there is no evidence that cortisone has any effect on fibrous tissue it is known to inhibit the formation of exudate It therefore seems essential to give it as soon as possible after tuberculous meningitis has been diagnosed Not only is it necessary to prevent the mechanical obstruction caused by the exudate, but the associated endarteritis and neurological damage resulting from it are unlikely to be reversible except in their earliest stages

Houghton (1954) has shown that prolonged courses of corticotrophin can be safely given to tuberculous patients while they are on full antibiotic treatment, his patients had pulmonary tuberculosis and were given corticotrophin for drug sensitivity He observed that corticotrophin not only dealt with the allergic manifestations but also "revolutionised" the patient's morale Jahn et al (1954) describe the use of corticotrophin and cortisone with antibiotics in the management of overwhelming infections such as peritonitis, meningococcal meningitis, and lobar pneumonia

Several reports have now been published abroad describing the use of cortisone or of corticotrophin in tuberculous meningitis Shane and Riley (1953) reported eight cases treated with cortisone in addition to the usual antibiotics (five of these were not treated with intrathecal streptomycin) These workers thought the cortisone had a beneficial effect on the course of the meningitis Bulkeley (1953) described the use of corticotrophin in thirty one cases of tuberculous meningitis in children Although it is not clear from the analysis that corticotrophin and not isoniazid was responsible for the improved mortality-rate in that series, at least it is evident that corticotrophin can be given to such patients without mishap Wasz Höckert (1954) has used cortisone and intrathecal hydrocortisone in the treatment of tuberculous meningitis in Helsinki, it is described as "routine" treatment in his unit now de Lavergne et al (1954) report its use in eighteen patients with tuberculous meningitis

Our two groups of patients can conveniently be compared under three headings the patient's general condition, the changes in the C S F, and the neurological complications All the patients who were given cortisone showed a very striking and early clinical improvement Whereas those treated conventionally (the first six patients) remained confused, uncooperative, and miserable for a week or ten days after beginning treatment, those who were given cortisone at the start were fully oriented, alert, and cheerful within two or three days The E S R of the cortisone-treated patients fell noticeably sooner, though this may have been a non-specific effect of the hormone Their appetites improved earlier than those of the controls, they gained weight more rapidly, and they clamoured to be allowed to get up within a week or two

The C S.F findings differed in the two groups, in particular the cell count fell very much more rapidly in the patients on cortisone than in the controls This was not unexpected, since cortisone was given largely to prevent a severe cellular response in the meninges At the same time, in some of the patients on cortisone the C S.F sugar level rose to normal very early, this also may have been a non specific effect of the hormone and might not necessarily indicate recession of the tuberculosis

There was a striking difference between the two groups in the incidence of neurological complications Of the controls one died and three have permanent stigmata, whereas all those treated with cortisone recovered completely without complications

The prolonged administration of cortisone may be attended by retention of salt and depletion of potassium Clinical evidence of this may be anticipated by the weekly estimation of serum electrolytes All patients treated with cortisone should be given additional potassium chloride by mouth The catastrophe of suprarenal failure may be avoided by covering the withdrawal of c[illegible]e by a short course of corticotrophin The danger of lighting up an old infection, such as osteomyel is real, and careful inquiry should be made into patient's previous illnesses Every precaution must taken to protect a patient on cortisone from acq secondary infection, since he may be unable to loca it adequately, and septicæmia may result

The danger of disseminating tuberculosis throu the body may be advanced as a contra indicatio cortisone therapy in tuberculous meningitis How many patients with this disease also have miliary t culosis, in them the process could hardly be disseminated Indeed, with effective antibiotics c sone therapy may accelerate recovery by rendering tubercle bacillus more accessible, it is less likely become walled off inside caseous material surround by a fibrous wall and with a poor blood-supply In patient with tuberculosis or any other infection trea with cortisone the appropriate antibiotics must continued after withdrawal of the hormone

Although it is not strictly relevant to the issue treating tuberculous meningitis with cortisone, we that mention must be made of the present trend withholding intrathecal streptomycin from select cases Some cases of tuberculous meningitis can d be "cured" without intrathecal streptomycin, provi that they are treated with full doses of oral and intramuscular streptomycin Early cases are in which there is the greatest incentive for withh intrathecal therapy It is not by any means esta that this is safe in all cases, however, and most treating tuberculous meningitis are giving intrathe streptomycin for at least four to six weeks Wh course is adopted, we believe that there is enough ev to show that the addition of cortisone to the trea of tuberculous meningitis has important advanta and merits further trial in a larger controlled series

## Summary

In this report six consecutive cases of tub meningitis treated by routine methods are comp with the next six patients admitted with this disea who were treated in the same way except that corti was added

Neurological complications occurred in four of t six control patients, and one of these died The patie treated with cortisone all recovered completely, with any neurological complications, and their clinical impro ment was much more rapid than that of the controls*

No complications of cortisone therapy were

Cortisone must be given from the beginning of t ment and with full antibiotic cover, which should conti for several weeks after the cortisone has been withdra

A more extensive clinical trial should be underta into the value of cortisone in the treatment of tubercul meningitis

We wish to thank the workers at the Whittington Gr Laboratory for their coöperation, Dr Arnold Bloom for advice about two of our patients, and Miss E M Mar for help with the foreign references

* Since the preparation of this report the last case (12) of the has developed spinal block and impairment of vision althou is otherwise well Only much greater experience of the complications could show whether cortisone reduces th incidence or could avert them if continued for a longer per

# KIN REACTIONS BENEATH ADHESIVE PLASTERS

BRIAN RUSSELL
Lond., F R C P D P H
PHYSICIAN IN-CHARGE

N A THORNE
M D Lond M R C P
SENIOR REGISTRAR

SKIN DEPARTMENT LONDON HOSPITAL

LTHOUGH medical and surgical plasters have been d for many years comparatively few clinical investi ions have been undertaken into the skin reactions eloping beneath them

eck et al (1948) described three types of reaction duced by adhesive tape (1) a fleeting reaction cting mostly hairy areas due to the mechanical uma of removing the tape (2) a specific sensitivity to or more ingredients of the plaster and (3) a reaction to change in pH and to the growth of bacteria on the beneath the plaster

Humphries (1947) has shown that moulds and bacteria w beneath ordinary adhesive plasters By adding salts of propionic acid and of caprylic acid to ordinary ster he found that of 130 patients who reacted to the ginal plaster only 5 reacted to the enhanced one reased tackiness was also noted after the plaster had n in position for seven days this might be due either the added fatty acids or to the decrease of maceration sequent on the reduction of bacterial flora beneath the ster Gaul and Underwood (1949) were unable to stantiate the observation that the incorporation of tericidal substances in the adhesive mass tended to rease the incidence of adhesive-tape dermatitis

eck et al (1948) found that the pH of normal skin was the pH increased to 6 3 after seven days and to after fourteen days beneath ordinary plaster but only 5 7 after seven days and to 6 4 after fourteen days eath plaster to which fatty acids had been added e bacterial flora decreased beneath both plasters but ecially beneath the one containing fatty acids

We consider that at least five types of reaction may elop beneath adhesive plasters owing to the following ises

1) Trauma of removal
2) Irritation by the adhesive
3) Retention of sweat and serous discharges on the skin ding to maceration of the horny layer
4) Favourable or unfavourable disturbance of the bacterial a by selective antibacterial action of some constituent the spread
5) Eczematous sensitisation to some substance in the esive spread or in the rubber

## Trauma of Removal

The traumatic reaction of removal occurs mostly at sebaceous orifices and is manifested as follicular ules with some diffuse or blotchy erythema It is atest with very tacky plasters and becomes milder if plaster has remained in situ for more than five days e reaction develops a minute or two after removal of plaster particularly at hairy sites and if a plaster vent has not been used to assist removal It has to be ferentiated from the reaction of irritation which elops only after a plaster has been in situ for some ee to five days and is then seen immediately the ster is removed Although Glick et al (1948) have ommended propylene glycol ethyl ether as a non gic and non inflammable remover of adhesive plaster have found that ether is entirely satisfactory for this pose provided the danger of its inflammability is preciated

## Irritation from Adhesive

rritation effects show as red papules and pustules, netimes with moist pink areas but without vesiculation e reaction is due to mechanical stimulation of the mation of keratin by the adhesiveness of the spread or by some chemical constituent of the adhesive mass There is also interference with desquamation The sweat-ducts are obstructed at their orifices along the epidermal ridges, and there is a milder hyperkeratosis and plugging of the ostia of the pilosebaceous follicles This reaction is more pronounced in sweaty people and in hot humid surroundings It appears clinically five days or more after the plaster has been applied but Peck et al (1951) observed histological changes within three days of the application of a plaster Any pre existing acne at the site of application of the plaster may be aggravated within forty eight hours giving a papular or papulopustular reaction (fig 1D)

Rubin (1949) showed that hyperkeratosis could be produced by slight continuous mechanical irritation —e g from the small range of movement of adhesive tape over the skin Another factor may well be the kerato plastic properties of certain chemicals particularly coal tar derivatives Thus chlorinated phenols are known to stimulate the formation of keratin and in this category is chloroxylenol which is contained in liquor chloroxylenolis *B.P* (roxenol) and in Dettol 'Germosan Neo monsol 'Osyl Streph Zant and several other proprietary antiseptics This substance has in the past been incorporated in plasters by some manufacturers

Infection often develops in the ducts and follicles beneath the ostial obstructions either mild when it is due to *Staphylococcus saprophyticus* and other sapro phytes or frankly purulent when it is due to *Staph pyogenes Pseudomonas pyocyanea* or *Proteus vulgaris* The process is analogous to that of miliaria rubra ( prickly heat )

We have tried to discover if there is any quantitative relationship between the adhesiveness of a plaster and its irritating effects on the skin For this purpose plaster discs of three known degrees of adhesiveness were applied to the backs of 31 students in random fashion over the scapular regions, and the number of papules beneath each disc was counted after it had been in position for a week If part of a patch became detached, the fraction of adhering remainder was estimated and the papule count was adjusted to what it would have been if the whole patch had remained in contact with the skin The results are summarised as follows :

| *Adhesiveness (G per sq inch)* | *Average no of papules per 0 6 sq cm* |
|---|---|
| 705 ± 65 | 14 7 |
| 445 ± 40 | 12 3 |
| [illegible]00 ± 80 | 11 1 |

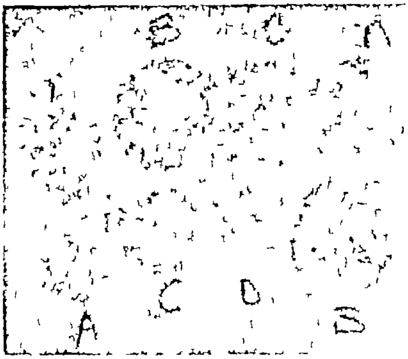

Fig 1—Patch-tests made with : A, standard plaster ; B plaster without chloroxylenol ; C, standard plaster ; D plaster made with deproteinised rubber Note positive eczematous response to A B and C, and effect of irritation alone of D probably due to coincident acne vulgaris.

The figures (which are not recorded here) have been considered statistically by Mr E C Fieller, who has expressed the view that they show quite conclusively the liability of the number of papules to increase with the adhesive strength of the plaster This does not exclude the probability that plasters of equal adhesive strength may vary in their tendencies to irritate by virtue of other differences in their physicochemical properties, and we hope to study this problem further when suitable plasters of equal adhesiveness but of different composition can be provided

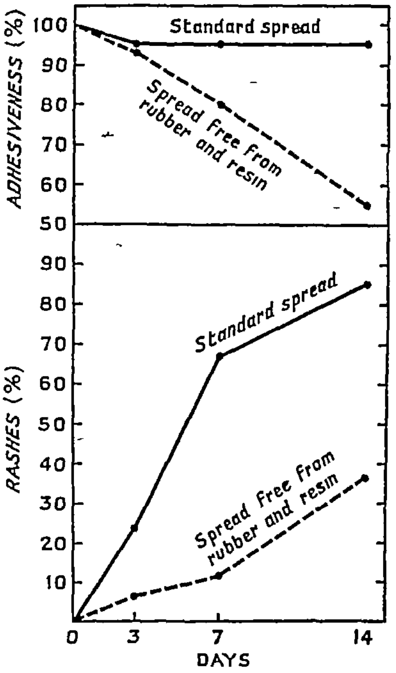

Fig 2—Incidence of rashes according to adhesiveness of plaster

Fig 2 compares the incidence of rashes when very adhesive plasters and less adhesive plasters are applied The plasters used were (1) a porous plaster of standard spread, and (2) a porous plaster said to contain neither rubber nor resin It will be observed that there were far fewer rashes from the latter plaster (37%) than from the former (85%), but its adhesion at the end of fourteen days was only 55% against 95% with the standard spread We have already indicated that the reaction of irritation depends inter alia on adhesiveness The plaster with only 55% adhesion is effective as a bandage wound round a limb but relatively ineffective for small patch dressings, and it should be called "semi adhesive" to differentiate it from "fully" (or 95%) adhesive plasters

We found that waterproof and ordinary plaster approximately similar adhesiveness produced much same number of papules, suggesting that the opera factor is the physicochemical properties of the pl constituents and not the degree of permeability of t backing material

One patient (case 25 in table) gave strongly pos reactions to the plaster mass, all constituents, ben and distilled water He had dermographia, and r developed at all sites It was considered that this wa example, not of contact eczematous dermatitis, but dermographia caused by the trauma of removing patches

### Retention of Sweat and Discharges

Retention of sweat and serous discharges may l to maceration of the horny layer, infection, or infec eczema Peck et al (1951) found that a propion caprylate fatty-acid solution applied to the skin be the application of plasters diminished the incidence erythema, œdema, and oozing but not the number papular reactions At the same time, the bacterial f was noted to be progressively reduced according to number of applications of the fatty acid solution have made patch-tests on 35 students with porous non porous adhesive plasters, with and without 0 zinc propionate and 0 6% zinc caprylate incorpora Plasters with fatty acid added produced a slightly r incidence of rashes (with the porous plasters but with the non porous ones) (fig 3) The incider rashes was slightly less with porous than with non adhesive spreads up to seven days but not sub A waterproof plaster produced the highest incidence rashes after a week, but the difference betwee curves was so slight as perhaps to be insignifica "Porous" bandages are only partially porous, th leave uncovered only a small proportion of the sw ducts and sebaceous follicles They have the degree of impermeability between perforations as l similar non porous bandages all over their surface certain circumstances the perforations may be obstructed after a few days by detritus or disch Nevertheless Scheffler and Lindner (1952), in a stu 100 patients, found that porous plasters were tolerate best E M Bavin (personal communication) has that the permeability of non-porous plasters to vapour is 100 G per sq metre per twenty four h and of porous plasters 3500 G per sq metre per t

hours The permeability is estimated by measuring ;ain in weight of a Polythene canister filled with um chloride, which has a lid with a circular hole ı in diameter covered with the adhesive tape being d The canister is kept under standard conditions )°C temperature and 90° relative humidity and is hed at regular intervals

### Disturbance of Bacterial Flora

ıe bacterial flora may be disturbed when manufac 's incorporate an antiseptic—e.g , chloroxylenol—in adhesive spread Chloroxylenol is a potent bac ide against *Streptococcus hæmolyticus* but much less 'e against *Staph pyogenes* and almost inactive against *ɔyocyanea* and *Proteus vulgaris* (*Extra Pharmacopœia* ) This disparity of action against different organisms predispose to staphylococcal proteus or pyocyanea :tion ( ecological drug eruption) or to the pro ion of a bacterial eczema perhaps with secondary spread "autolytic" eczema

### Eczematous Sensitisation

ɔntact eczematous reactions to some chemical con ıent of the adhesive spread or of the rubber are h rarer than reactions caused by irritation They ılop after a latent period of days on the first exposure, fter a few hours with subsequent exposures, and are ıcterised by erythema œdema, and vesiculation constituents of plasters which are most likely to be onsible include colophony resin (rosin) crêpe rubber ked rubber rubber antioxidants plasticisers and septics which some makers have thought it wise to rporate Of the other constituents wool fat (lanolin) nown to be a very occasional sensitiser in 1 14% of ımatous people but much less than this in the general ulation (Sulzberger et al 1953) Liquid paraffin zinc oxide are unlikely to upset the skin

ı trying to find the commoner causes of contact-matous reactions from adhesive plaster we applied individual constituents dissolved in arachis oil on ll squares of gauze held in place by an adhesive of irritative and sensitisation potential to people known ɔo sensitive to the plaster mass Negative results ı obtained in 9 of 10 cases the exception being a tive reaction to colophony Further trials were then o with the constituents dissolved in benzene and tive results were obtained in most of the patients ɔd

ho substances were made up into solutions containing ·1 ml the amount of each constituent present in ı cm of the composite plaster The results were rved at forty eight hours and once more at to seven days The substances tested were as :lws

(1) Benzene (control)
(2) 0 1% Flectol H a plasticiser and antioxidant
(3) 0 25% chloroxylenol
(4) 5% crêpe rubber containing no antioxidant
(5) 5% smoked rubber containing very little antioxidant, probably of hydroquinone type and some oxidation products of the smoking process
(6) 5% colophony resin, the chief constituent of which is abietic acid said by Schwartz et al. (1947) to be an irritant to hypersensitive people

The results were as follows

| | |
|---|---|
| Number of patients tested to constituents in benzene | 10 |
| Positive to 5 0% colophony | 4 |
| Positive to 0 25% chloroxylenol | 3 |
| Positive (?) to 5·0% crêpe rubber | 1 |
| Positive to 5·0% smoked rubber (2 ? positive) | 3 |
| Positive to 0 1% flectol H | 0 |
| Positive to benzene | 0 |
| Positive to colophony and to chloroxylenol | 1 |
| Positive to crêpe rubber to smoked rubber and ? to chloroxylenol | 1 |
| Positive to multiple factors (probably irritant effect) | 1 |
| Positive to every patch (due to dermographia) | 1 |
| Negative to all constituents | 3 |
| Invalid (patches fell off after a few hours) | 1 |

Trials have been made with deproteinised rubber plasters and with chloroxylenol free plasters on suitable patients People sensitive to chloroxylenol tolerate a plaster free from this substance, and people sensitive to either crêpe or sheet rubber are tolerant of adhesive dressings made with deproteinised rubber (fig 1) On the other hand, people sensitised to colophony have continued to react to plasters free from chloroxylenol or from protein fractions of rubber The results were as follows

| | |
|---|---|
| Positive to plaster with chloroxylenol and negative to plaster without chloroxylenol | 2 |
| Positive to plaster with rubber proteins and negative to plaster without rubber proteins | 5 |
| Positive to plaster with rubber proteins and doubtful to plaster without rubber proteins | 4 |
| Positive to plasters with and without chloroxylenol and with and without rubber proteins | 3 |

(Rubber is deproteinised by a complex process of ammoniation and centrifugation which throws out the proteins salts and possibly the natural antioxidants Treatment with trypsin hydrolyses any remaining protein after which further centrifugation is done followed by coagulation with acetic acid )

From these tests the following conclusions were drawn :

| | |
|---|---|
| Sensitive to chloroxylenol | 6 (1 7) |
| Sensitive to colophony | 5 |
| Sensitive to rubber | 5 (1 7) |
| Sensitive to rubber-adhesive complex | 1 (1 2) |
| Multiple sensitivity | (1 1) |
| Irritation effects | 4 |
| Irritation effects through dermographia | 1 |
| Undetermined causes (of which 3 were tested to ingredients in arachis oil and 1 was tested to ingredients in benzene in the 5th the effects were probably due to irritation) | 5 |

For the detailed results see the accompanying table

The foregoing clinical results are supported by the results of experiments on animals made in the laboratories of Smith & Nephew Research Ltd by Mr E M Bavin B.SC., and Miss B James B SC to whom we are indebted for the following summary of their work

> Our technique is to apply the substance by inunction to a clipped but not depilated area of the back of the guinea pig using 0 1 ml of a solution of the constituent in arachis oil. This dose is repeated daily for twenty-eight days. The guineapigs are then left for a further fourteen days at the end of which *pontamine sky blue dissolved in physiological* saline solution, is injected intravenously and two minutes later a further dose of the constituent is applied to the skin After an hour the guineapigs are killed and the skin at the site of application is reflected from the back A definite blue patch is considered as a positive reaction but a very slight blue coloration is neglected because it can be caused by excessive handling of the skin This technique was adapted from the work of Miles and Miles (1952) and Halpern (1953)
>
> In control experiments with foreign serum or chemical substances—e.g nitrosodimethylanilin and dinitrochloro benzene—which are known to produce sensitisation we obtained strong reactions by this technique The

of our work with adhesive plaster constituents are given in the following table

| *Constituent* | *Positive reactions* |
|---|---|
| Colophony | 2/10 guineapigs |
| Flectol H | 0/5 ,, |
| Chloroxylenol | 4/10 |
| Pale crêpe rubber | 1/10 |
| *Arachis-oil solvent* | 0/10 ,, |

From these results it will be seen that chloroxylenol is the most active sensitising agent, and that colophony resin and pale crêpe rubber produced a low degree of sensitisation "

In modern dermatological practice in Great Britain chloroxylenol, in the form of roxenol, is one of the commonest causes of contact eczematous dermatitis In some of the patients sensitised to chloroxylenol a history was obtained of a reaction to adhesive plaster followed by a reaction to roxenol used as an antiseptic, or vice versa, and patch-testing confirmed that it was the chloroxylenol fraction of the adhesive mass that caused the reaction We have even used plasters known to contain chloroxylenol as readily available patches for confirming sensitisation to roxenol

A patient presented with a history of a cut palm which had been treated with a well known proprietary brand of roxenol, after which a rash developed around the wound This had been treated with a roxenol ointment, and the dermatitis spread locally The patient wore cotton gloves as dressings which were immersed in roxenol by his wife before he used them Subsequently the rash developed all over both hands which became reddened, swollen, and desquamating in glove distribution with a sharply demarcated upper limit This patient also used roxenol as a shaving lotion in spite of the fact that it stung him when applied Patch tests with adhesive plaster containing chloroxylenol and another free from this substance gave positive and negative reactions respectively Subsequent avoidance of chloroxylenol brought about a steady improvement in the dermatitis

We have not yet had the opportunity to test patients with plasters modified only by the substitution of some other resin for colophony, but we have not observed any contact eczematous reaction to a plaster said to contain neither resin nor rubber

We believe that contact eczematous reactions due to plasters could be avoided, or rendered still rarer than they are, by using deproteinised rubber, by abandoning the practice of incorporating antiseptics with sensitising properties, and by substituting for colophony either a natural or a synthetic resin of lower sensitising potential

## Comments

The following difficulties may be met when interpreting results

(1) Reactions of removal and of irritation must be differentiated by inspection of the patch immediately after its removal

(2) Negative reactions with constituents and positive ones with the plaster mass may be due to some chemical interaction between constituents in the composite plaster or to the use of an unsuitable suspending agent for the ingredients under test Peck et al (1951) do not state whether the many ingredients with which they made patch tests on patients known to be sensitive to plasters were applied alone or in suspension, possibly the use of an unsuitable suspending agent may have led to their completely negative results

(3) In applying the constituents it is necessary to use an adhesive with a small sensitising potential For this purpose we have used the above mentioned plaster containing neither rubber nor resin but of relatively poor adhesive quality, on one occasion it was not even sufficiently adhesive to retain the patches in position for forty eight hours Negative patch tests have been obtained with this plaster in all cases of sensitivity to other plasters

(4) When multiple patch tests are made with plasters, if the cause is not soon determined there comes a time when the patient may begin to react in a non specific fashion to most or all of the patch test substances In these circumstances testing should be suspended for several weeks or even

## Summary

There are at least five types of reaction to adh plasters

Papulopustular reactions of irritation are more erous as the adhesiveness of the plaster is incre Other physicochemical properties of the plaster are also probably important

Reactions of eczematous sensitisation are most monly due to colophony, rubber proteins, antisepti complexes in the plaster mass Reactions to the plas or to the antioxidant have not so far been obs We have not tested our patients for sensitivity to

These reactions are rendered rarer by using d teinised rubber, abandoning the use of chlorox and substituting for colophony some other resin of sensitising potential

It is a pleasure to acknowledge the help afforded by Sm Nephew Research Ltd, who supplied much of our about substances commonly used in the manufactu adhesive plaster and provided some of the materials this investigation We also wish to thank Mr E C F for his statistical advice The photograph was take Mr P Broadbery at The London Hospital We also the many anonymous students who volunteered for p testing

# MASKED EPILEPSY

HUGH R E WALLIS
M D Camb, M R C P, D C H
CONSULTANT PÆDIATRICIAN, BATH CLINICAL AREA

IN 1950 the Bristol Medico Chirurgical Society sidered at a clinical meeting a boy, aged 8½ years had recurrent attacks of pain in a leg Epilep diagnosed and confirmed by electro encephalog Later the boy began to have overt major ep attacks Treatment with phenobarbitone stopp fits and the attacks of pain

On seeing this case I first became aware that e may consist of sensory manifestations only Dur past three years, while engaged in consulting pæ practice, I have seen several cases in which assumed unusual forms, and I suspect that probably more common than is generally realised

The term " masked epilepsy " is now used to psychic seizures, psychomotor disorders, or temporary changes in personality causing aggressiveness In the past it was used in a sense, as by Sir Frederic Still (see below) Such seem to be common enough to justify resurrec the term to denote cases in which symptoms pains in the body or head, vomiting, or even are the only manifestations of epilepsy

It has long been recognised that epilepsy ma itself in various ways without convulsions or uncon ness Trousseau (1868) reported the case of a bo 10 years, who had attacks several times a day he complained of pressure in the pit of the s vomiting, giddiness, and pallor Trousseau d epilepsy but could convince no one of this until ıter when the boy had several attacks of undoubted rand mal

Sir Frederic Still (1912) wrote:

> In addition to these categories of major and minor pilepsy there is another which often passes unrecognised or a time the so called épilepsie larvée or masked pilepsy I have seen several cases in which the chief ymptom was a sudden pain in the navel or epigastrium g :—William B aged 10½, since the age of 9 months has ıad sudden attacks of pain in the epigastrium this lasts few seconds, during which there is sudden pallor succeeded y flushing after which the boy becomes pale and asks to ie down and goes to sleep for a long time This occurs everal *times a day With large doses of bromide these attacks* vere greatly reduced in number and sometimes checked ltogether for several weeks.

Kinnier *Wilson (1940) was aware of the occurrence of* uch attacks but gave his opinion somewhat cautiously

> Some of these alleged visceral equivalents might be pileptic *and not migrainous, others comparable to a tabetic* rises, still others based on unrecognised lesions.

Moore (1944 1945 1950) in America has reported everal cases which presented with abdominal pain He says:

> Most of the patients suffering from this disorder have in he past been hospitalised numerous times, subjected to scores of examinations and varied forms of therapy without relief and have had needless laparotomies done Only too frequently they have been considered as psychoneurotics or *nalingerers*

Livingston (1951) claims that Moore first described the syndrome of abdominal epilepsy This is not so *Trousseau did that seventy five years earlier*

Davidson and Lombroso (1952) described cases of epilepsy in children characterised by paroxysmal disturbances of temperature regulation producing both yperthermia and hypothermia

Mulder et al (1954) reported 100 patients who had aroxysmal visceral symptoms either as the aura of an pileptic attack or taking the place of an attack They tate

> The bizarre nature of the complaints frequently led to diagnosis of localised visceral disease Correct diagnosis lepends on the recognition of the paroxysmal occurrence of he symptoms and their inappropriateness to the total ituation together with the association of other symptoms nd findings of cerebral involvement

hey also quote Hughlings Jackson (1888) who wrote:

> The great thing as to the diagnosis of epilepsy is not the uantity of the symptoms, nor the severity of the fits, but the aroxysmalness.

In this country if the diagnosis is ever considered t all masked epilepsy is classed as extremely rare onway (1951) could find only 1 case among 250 children ged more than 2 years who attended as outpatients t The Hospital for Sick Children Great Ormond Street ondon with abdominal pain as the main complaint he six most common diagnoses were as follows

| *Diagnosis* | No *of cases* |
|---|---|
| Colic of unknown cause | 73 |
| Mesenteric adenitis | 54 |
| Constipation | 48 |
| Periodic syndrome | 21 |
| Psychogenic | 23 |
| Enteritis | 13 |

Perhaps the colics of unknown causation periodic ndromes and psychogenic cases *concealed a few* fferers from masked epilepsy

## Case reports

### SO-CALLED CYCLICAL VOMITING

**Case 1**—A boy aged 8 years came to my notice when his ster was brought into hospital with status epilepticus rom the age of 2½ years he had had recurrent attacks of vere vomiting Sometimes during these he became unaware his surroundings for as long as thirty minutes and occasionally the right side of his face twitched His mother was alive and well His father had occasional bilious attacks His sister was aged 6 years and had had two attacks of *vomiting and unconsciousness on previous occasions* The boy had been seen once by a consultant who wrote From the family and personal history I guess this is a form of cyclical vomiting which may well lead on to migraine later in life When his sister came into hospital it was found that she had epilepsy and it was decided to investigate the boy also

*On examination* he showed no abnormal signs in the central nervous system. His blood pressure and urine were normal The Wassermann reaction was negative and radiography of the skull showed no abnormality An electro-encephalogram showed a highly abnormal record indicative of epilepsy; there were no focal or localised abnormalities.

*Treatment* with phenobarbitone has controlled the attacks and when he is given gr 1½ daily he has no trouble

*Comment*—*The history of unconsciousness and twitch*ing of the face should have stimulated further investigation which would have led to the correct diagnosis earlier The epilepsy can scarcely be called masked but merely unrecognised

**Case 2**—A girl suffered from frequent bilious attacks from *the age of 8 years. Her father had had similar attacks in* childhood She had several attacks of acute tonsillitis and in January 1949 her tonsils were removed In March 1949 she developed acute nephritis and was admitted to hospital The disease ran a mild course and she was discharged after seven weeks, apparently cured The registrar's summary of her stay stated She has been inclined to get attacks of vomiting associated with pyrexia up to 102 F for which we have been unable to find any very satisfactory cause At home she continued to have bouts of pyrexia and vomiting Sometimes these were accompanied by right-*sided headache and twice she had what were termed black* outs Her family doctor sent her to a consultant as a case of cyclical vomiting No abnormal physical signs were found apart from carious teeth and no firm diagnosis was made Later the attacks were accompanied by severe lower abdominal pain and diarrhœa The family doctor then referred her at the age of 12 years, for a further opinion He thought that the attacks did not fit in with cyclical vomiting but were psychological in origin though he admitted that he could detect no cause of mental conflict Further questioning of her mother revealed that during the attacks *she usually became unresponsive sometimes unconscious* and occasionally incontinent of urine The family doctor had given her phenobarbitone gr ¼ daily for six months and during that time she was free from attacks For some reason he stopped it and the attacks returned

*Investigation* showed no abnormality in the central nervous system, blood pressure urine radiograph of skull or Wassermann reaction An electro encephalogram showed an abnormal record indicative of epilepsy there were no focal abnormalities, nor was there any lateralisation

*Treatment*—She was treated with phenobarbitone and had *one attack of vomiting in two years* A second electro encephalogram taken eighteen months after the first showed some epileptiform features but there is considerable improvement since the previous record the patient would appear to be well controlled by anticonvulsant drugs

*Comment*—The epilepsy was masked at first and caused attacks of pyrexia and vomiting Later the clues of unconsciousness incontinence and improvement under treatment with phenobarbitone led to a diagnosis of epilepsy even before the electro-encephalogram was taken It seems that pyrexia may be one of the manifestations of epilepsy It might be argued that the pyrexia caused the epilepsy; but no explanation was found for the pyrexia though by chance it was observed in hospital while she was suffering from another disease In fact the pyrexia took the place of convulsions

### HEADACHES

**Case 3**—A boy aged 4 years with no relevant family history was sent into hospital because of attacks of headache sleepiness and vomiting which had begun at the age of 1 year and had recently become more frequent At first there were intervals of 4 6 months between the attacks but just before his admission he had three attacks in fourteen days The onset was with headache after about thirty minutes he went to sleep at intervals he woke up and vomited, then went back to sleep He became pale, yet his skin was hot and perspiring There was no correlation with the time of day, meals or exercise

*Examination and investigation* revealed no abnormality His blood sugar level three hours after a meal was 108 mg per 100 ml An electro encephalogram showed a record just outside normal limits with mild epileptiform features, but it is not indicative of this condition , there were no focal abnormalities "

*Treatment* —Since it was felt that the attacks were probably epileptic, he was treated with phenobarbitone, and after three months he was much improved His mother stated that he had had no attacks at all and that he was " a different child " She also said that he used to grunt and nod his head when asleep but did so no longer

*Follow up* —Another electro encephalogram, taken three months after the first, showed ' a record which remains outside normal limits and is now definitely suggestive of epilepsy '

**Case 4** —A girl had, at the age of 5 years, a febrile illness which was not diagnosed For three months after this she complained of headaches at intervals of about a week During the attacks she lost her appetite, became pale, and felt sick, but did not vomit She had had two convulsions in infancy which were ascribed to teething and were ignored Her brother, aged 17 months, had already had one convulsion Her mother had had shock therapy for schizophrenia, and a first cousin on her mother s side had epilepsy

*Examination and investigation* revealed no abnormality except possibly that some increase in intracranial tension was visible in the radiograph of the skull There was no papillœdema An electro-encephalogram showed " an abnormal record indicative of epilepsy , there were no focal or localised abnormalities "

*Treatment* —The girl was treated with phenobarbitone After three months her mother reported that the headaches were less frequent, and after another three months they had disappeared The mother then volunteered the statement ' She is not the same child She is not noisy and mischievous any more She used to get panic stricken but doesn't now "

*Comment on cases 3 and 4* —Note the alteration in behaviour observed by the parents when these two children were treated adequately The idea of an epileptic personality as a precursor to epilepsy has been discarded, but these two cases suggest that there may be such an entity It is possible that personality changes may be the only manifestation of epilepsy

**Case 5** —A boy, aged 9 years, had three years' history of headaches They occurred every day and lasted from one to twelve hours He went pale but had no nausea or vomiting Neither aspirin nor codeine tablets relieved him At the age of 2 years he weighed only 21 lb and was referred to a consultant, who found no abnormal physical signs and made no investigations or diagnosis His mother had had fits up to the age of 7 years

*Examination* revealed a small boy weighing 44 lb , but no other abnormalities except a positive tuberculin test and a doubtfully opaque left antrum on radiography An ear, nose, and throat surgeon considered this last finding of no importance The Kahn test was negative The boy was sent home from hospital with no definite diagnosis

*Later history* —He continued to have headaches, though not so often as before A year later he began to vomit, and epilepsy was considered Electro encephalography showed an abnormal record definitely suggestive of epilepsy , although there was some localisation to the parieto temporal lobes with a left sided preponderance, the degree of asymmetry was not great '

*Treatment* —He was treated with phenobarbitone His headaches became fewer but, when they did occur, more severe An attempt was made to use primidone, but this was abandoned because of the side effects The use of sodium phenytoin in addition to phenobarbitone has proved successful

ABDOMINAL PAIN

**Case 6** —A boy aged 8 years whose mother suffered from migraine had sick headaches for two years and then had one which was accompanied by abdominal pain He was surgeon who stated that there was no appendicitis

Later on he was investigated in the pædiatric outpatient department, and no abnormality was found in any system Migraine was tentatively diagnosed It was suggested that either codeine or ergotamine might be tried During the next eighteen months he had repeated attacks of vomiting and abdominal pain There was no relief from codeine Ergotamine was not tried He was an only child, and his family doctor felt that his troubles might be magnified by his mother He sent him to another surgeon for advice about the appendix This surgeon too refused to operate, and the boy was refer to the medical side again

*Investigation* revealed no abnormality, but it was consider that the abdominal pain might be an epileptic equivale An electro encephalogram showed " a definitely abnor record indicative of epilepsy , there were no foc abnormalities "

*Treatment* —The boy was treated with phenobarbitone and during six months has had no attacks

*Comment* —But for the vigilance of two surgeons the boy would probably have had a normal appendix removed This case shows the importance of full investigation even in cases where there is every reason to suspect that psychological difficulties are concerned

**Case 7** —A girl, aged 5 years, was referred by the school doctor for attacks of abdominal pain which was severe enough at times for her to be sent home from school She had had them since the age of $2^{1}/_{2}$ years They came on about th or four times a week, making her scream She felt sick bu never vomited One of her mother's brothers had had simil symptoms in childhood, and at the age of 20 began to hav epileptic fits, which continued at intervals for thirty years

*Investigation* revealed no abnormality apart from larg tonsils The report on the electro encephalogram was " This is an abnormal record definitely suggestive of epi There were no focal abnormalities "

*Treatment* —The girl was treated with phenobarbitone has remained remarkably free from pain After a month treatment her mother said " She has not complained anything for four weeks, which is quite unusual for her '

## Discussion

### *Diagnosis*

It seems fair to say that the main symptoms in idiopathic epilepsy may be headaches, or vomiting, pains, or pyrexia, or a combination of any of They do not represent an aura but take the place of th convulsion and unconsciousness as epileptic manifestations If a child has any of these symptoms at intervals or for a long period and they cannot be explain an electro encephalogram should be taken Points the history which suggest epilepsy are a family tend to convulsions, pallor during the attacks, drowsine after them, and improvement when treated with anticonvulsants , but it is not necessary for these to present before pressing on with the investigation Th is, of course, no excuse for neglecting to make a th investigation to exclude other causes of the sympto In some cases pyrexia acts as a trigger for an attack epilepsy, and the cause of the pyrexia must be sou In all cases the possibility that a cerebral tumour m cause the symptoms must be borne in mind and exclud before idiopathic epilepsy is diagnosed

Patients are sometimes seen in whom a firm diagno of grand mal or petit mal is made but no abnorma is ever recorded in their electro encephalographic tracin Presumably the same may happen in masked epilep The diagnosis is then very difficult , but it may be m if there is a strong family history and the response treatment is satisfactory

### *Family History*

Of the 7 children reported here 4 had a history convulsions in near relations In addition a parent 1 of them had had recurrent vomiting in childho and a parent of another child had migraine In 1 case could no relevant family history be obtai In cases 1, 2, 6, and 7 there was a story of similar att which might have been masked epilepsy, in relations

*Age of Onset*

The age of onset varied from 1 to 8 years which is consistent with the usual onset of idiopathic epilepsy 'Three months' colic' investigated by Illingworth 1954) seems to be a baffling disease and it might be worth considering whether it is sometimes due to epilepsy Illingworth cites Still and Sheldon as stating that it sometimes leads to convulsions No cases of three months' colic have been met with in this nvestigation

*Treatment*

In this series phenobarbitone has generally proved successful in relieving symptoms In America either diphenyl hydantoin sodium or a combination of drugs is usually recommended. Blumberg (1954) describes a case where troxidone proved necessary This patient who had become a problem child was, when his abdominal epilepsy was controlled converted into a joy and a model child.'

It seems best to try first the least toxic drug available —i e phenobarbitone—and to give it in adequate doses Epileptic children seem able to tolerate large amounts of phenobarbitone without becoming sleepy whereas normal children cannot

*Incidence*

These 7 cases were met with in three years' consultant pædiatric practice, during which about 1400 new patients were seen either as outpatients or on admission to hospital The figures are of little value, however because in the early months cases must have been missed and classed as psychogenic or inexplicable, whereas later when general practitioners had realised my interest in such cases they might refer more than would normally come into the net A few more cases have been seen recently but have not been followed up long enough to merit nclusion here

*Cyclical Vomiting*

It is doubtful if this disease exists No genuine cases have been seen in this area in the past three years Investigation may reveal one of the following causes Abortus fever cerebral tumour islet-cell tumour of the pancreas recurrent neutropenia recurrent pyelitis, sinusitis or tuberculous mesenteric adenitis

In the first description of cyclical vomiting (Gee 1882) cases were reported of fitful or recurrent vomiting The notes nowadays would be judged inadequate but some of the patients may well have been epileptic Of the 5 for whom a family history was given 4 had near relations who had paroxysmal headaches or megrim

Hamilton (1951) has pointed out that one or other of the parents is not infrequently a victim of migraine Smith (1951) gave his experiences with 700 public school boys 108 of them had had attacks of vomiting before entry at the age of 13 and 13 of these developed migraine Smith stated

> The most dramatic migrainous sequel is epilepsy One boy who had habitual and often violent sick headaches suddenly had a severe epileptic fit in the school library He was treated with sedatives and had no further attacks

The only other boy who crossed the frontier from migraine to epilepsy continued to have attacks, because his father a well known surgeon (who had had similar attacks until the age of 17) was against phenobarbitone

These two (or three if we include the father) might well be called cases of masked epilepsy

*Migraine*

The relation between migraine and epilepsy has been described often enough and the electro encephalogram in migraine has been studied It is usually stated that the tracing is abnormal but not typical of epilepsy The main difficulty has been in diagnosing migraine accurately The cases and families described above seem indicate that two conditions cause paroxysmal headaches true migraine and masked epilepsy To the unsuspecting observer masked epilepsy will often seem to be migraine and no doubt in the past many cases have been so labelled

This surmise is supported by the following statement made by Critchley (1950)

> Prevention of attacks of migraine by medicinal means is often most disappointing Perhaps phenobarbitone is the safest bet Little if any benefit results from the administration of this drug at the time of an attack. The patient should persevere for two or three months before concluding that the drug is without avail

*Night Terrors*

It is well recognised that these are sometimes epileptic manifestations (Paterson 1944) In giving the history of patients with epilepsy parents often make some such statement as He sleeps badly, He is on the go all the time in his sleep ' and He jerks and twists about in bed " In some cases there is a history of this unrest at night in brothers or sisters who show no other indication of epilepsy Treatment with phenobarbitone usually controls it

*Electro-encephalography*

It is usually conceded that a normal tracing can be obtained from an undoubted epileptic and that a normal person may at times show an abnormal tracing, though with modern techniques this is becoming rarer Critics may complain that this makes it easy to invent a syndrome and to call it masked epilepsy The proof of the pudding is in the eating The considerable improvement which took place in these patients when they were treated with phenobarbitone confirms the epileptic nature of their illness Moreover none of them fitted any other diagnosis

Of the 7 cases 6 had no localising features but in case 5 the parietotemporal lobes seemed to be involved It is doubtful if localisation is of any value in this condition, though Mulder et al (1954) suggest that it may be

*Nocturnal Enuresis*

It has been suggested that nocturnal enuresis may in some patients be the only symptom of epilepsy Turton and Spear (1953) found an abnormally high percentage of epileptic tracings in a survey of 100 children who had severe enuresis Treatment with phenobarbitone rarely benefits such patients and the question may be considered to be still unsettled

*Psychological Causes*

Fielding (1749) wrote

> Every physician almost hath his favourite disease to which he ascribes all the victories obtained over human nature The gout the rheumatism the stone the gravel, and the consumption have all their several patrons in the faculty : and none more than the nervous fever or the fever on the spirits

The fashion has not altered, and nowadays abdominal pain is often put down to psychological causes Certainly pain in children sometimes has a psychological cause or reason for continuing but this is not common. It is very easy to call pain psychological whenever we do not understand its nature (cf Moore 1944 1945 1950) The state of a child who has a genuine pain which his parents and doctor cannot explain is sad indeed and after the passage of time he may well become neurotic Let us therefore seek ever more earnestly for causes and see if we cannot whittle down the core of abdominal pain of unknown origin.

*Telling the Parents*

People still have fear and horror of the word epilepsy Fits convulsions and seizures may be allowed but epilepsy not It is difficult to explain masked epilepsy to some parents and occasionally they will aggressively resist it Either we can attempt to educate parents into a realisation that epilepsy is not a slur nor inevitably associated with mental deficiency or we can glide over the problem by using such terms as "abdominal migraine"

### Summary

Cases are described in which epilepsy manifested itself as pain in the leg, so called cyclical vomiting headaches, pyrexia, and abdominal pain

This type of epilepsy is fairly common though often unrecognised, and many cases of cyclical vomiting and migraine may prove to be epileptic

The term "masked epilepsy" should be extended to include these phenomena

Treatment with phenobarbitone is usually successful

I wish to thank Dr H Lovell Hoffman for advice, and Dr E C Turton for his reports on the electro encephalograms

# SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD

## WITH MEGALOBLASTIC ANÆMIA DUE TO SPONTANEOUS ILEOCOLIC FISTULA

R W Wilkinson
M B Leeds, D C H, D.M R D
RADIOLOGICAL REGISTRAR, HAMMERSMITH HOSPITAL, LONDON

This is the first recorded example of subacute combined degeneration of the spinal cord with macrocytic anæmia and spontaneous ileocolic fistula Initially liver therapy cured the anæmia and arrested the neurological degeneration, and this position has been maintained without further liver injections after successful resection of the fistula The 3 published cases of anæmia and subacute combined degeneration of the spinal cord due to intestinal fistula all followed gangrenous appendicitis and all were fatal In the present case the discovery of the fistula after a barium meal rather than an opaque enema is unusual Free hydrochloric acid was present in the gastric juice, and there was an increased amount of fat in the stools Diarrhœa was not a prominent symptom The clinical picture was complicated by a duodenal ulcer

### Case-report

A woman aged 25 whose mother had died of pernicious anæmia, was first seen in 1941 complaining of nausea and vomiting shortly after meals During the next two years she lost 2 st in weight, and in 1943 an active duodenal ulcer was found radiographically, associated with normal acid secretion In April 1945, the patient complained of breathlessness difficulty in walking and a feeling of uselessness in the legs, hands and arms Her diet since 1943 had consisted mainly of eggs and milk

*On examination* she was pale and thin with bruising over the lower back and knee joints There was moderate pitting œdema of the ankles The liver was palpable one fingerbreadth below the costal margin The knee jerks and ankle jerks were absent, and the plantar responses were extensor [illegible] considerable disturbance of joint and position [illegible] lower and upper limbs and vibration sense was absent in the legs up to the level of the iliac crests Romberg's sign was positive No other abnormality was found

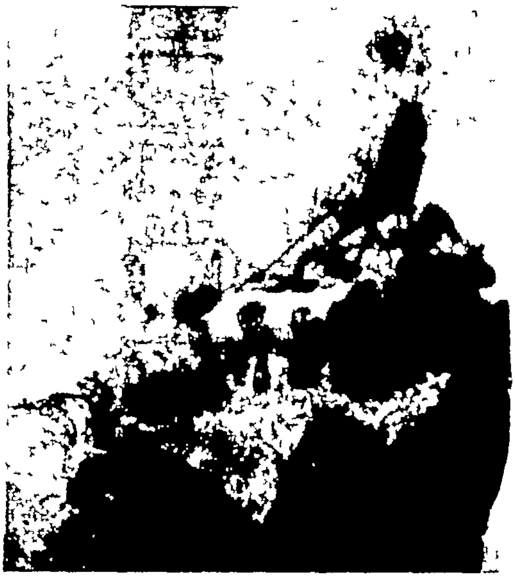

Fig 1—Film three-quarters of an hour after barium meal, showing communication between small bowel and middle of transverse colon and diverticula in small bowel

*Investigations*—Examination of the blood showed red cells 1,150,000 per c mm, with anisocytosis megalocytosis, and polychromasia, Hb 32% (4 9 g per 100 ml), white cells 2000 per c mm, Arneth shift to the right A van den Berg test gave a positive direct response Sternal puncture showed megaloblastic hyperplasia Fæcal fat on a normal diet was 76% and 28% of the dry weight of two random specimens Blood ascorbic acid 0 14 mg (normal 0 75 mg) per 100 ml Serum iron 26 8 µg (normal 98–112 µg) per 100 ml Plasma proteins 5 3 g per 100 ml albumin/globulin ratio 1 1/1 A test-meal showed that free hydrochloric acid was present.

*Treatment and Progress*—The patient was treated with crude liver extract parenterally and had a reticulocyte response of 34% the Hb increasing to 60% in a month by November, 1945, the blood picture was normal. At that time a further barium meal and follow through radiological examination was made which showed, in addition to the chronic duodenal ulcer, an ileocolic fistula and several diverticula scattered through the small intestine (fig 1) A contrast enema showed a doubtful irregularity in the middle of the transverse colon Treated with liver the patient remained well except for occasional attacks of mild diarrhœa lasting two or three weeks every two or three months. Medical treatment improved the abnormal neurological signs but did not entirely abolish them, with the result that by August 1948, the plantar responses were less briskly extensor, and sensory disturbance was limited to loss of vibration sense below the knees Repeat barium studies in November, 19 confirmed the presence of the fistula At that time the patient weighed 114 lb, her Hb was 94% (14 g per 100 ml) with normal red cell morphology, and the plasma protein was 6 5 g per 100 ml, with albumin/globulin ratio 1 The colloidal gold reaction of the serum was negative The total fæcal fat in a twenty four hour specimen was 46 0% of the dried fæces (on a normal diet)

*Operation*—The fistula was excised by Mr J C An F.R C S on Jan 22, 1951, and the peritoneal cavity was found to be obliterated by fine avascular adhesions Directly below the incision a fistula was found from the middle of the transverse colon to a loop of small bowel which could not be identified The fistula was excised and the normal continuity of the bowel restored

*Postoperative recovery* was uneventful and the patient was discharged ten days after the operation, liver treatment being discontinued

*Follow up*—The patient was seen again on March 12 1954 when she reported that she was very well and had gained a little weight Her red cells were 5,600,000 per c mm, with normal morphology, Hb was 94% (14 g per 100 ml), eucocytes were 5600 per c.mm. The neurological signs were unchanged. On March 15, 1954, her weight had increased to 140 lb. and she was in full-time employment. She had no nausea or vomiting and her bowels were regular with no diarrhœa. Her plantar responses were equivocal and her only sensory abnormality was some diminution in vibration sense over the lower legs. Her Hb was 84% (12·4 g. per 100 ml.) and the red-cell morphology was normal.

## Discussion

The presence of free acid in the gastric juice excludes the diagnosis of pernicious anæmia. Askey (1944) carefully reviewed 47 reported cases of pernicious anæmia with free acid and found none proved. The association of macrocytic anæmia with lesions of the bowel has been recognised for more than fifty years, cases being reported by White (1890), Wallis and Warfinge (1893), and Meulengracht (1929); but Faber (1895) seems to have been the first to suggest a causal relationship (Plum and Warburg 1939). The first recorded instance of macrocytic anæmia following intestinal anastomosis appears to be that of Little et al. (1929). The subject of macrocytic anæmia with intestinal stricture and anastomosis is well reviewed by Barker and Hummel (1939), who add 2 new cases and give details of 40 previously reported examples. Cameron et al. (1949) found 9 more patients in the published reports of the next decade and added 1 of their own. Wilkinson (1949) states that all cases of intestinal macrocytic anæmia would respond to liver if the marrow were megaloblastic, and this was the experience in the present case.

The combination of bowel lesion, macrocytic anæmia, and involvement of the spinal cord is much less common. Davis and Brown (1952) say of megaloblastic anæmias resulting from structural abnormalities affecting the small intestine: "Neurological complications are extremely rare, but a few cases have been recorded." Watson and Witts (1952) state that subacute combined degeneration of the cord occurs "in a fairly large proportion of patients," but give no details. However, in an earlier analysis of published cases Cameron et al. (1949) found "neurological signs" in 12 of 61 cases. This total includes 2 patients with subacute combined degeneration.

The first of these (Little et al. 1929) was in a man aged 20 who had two entero-anastomoses for intestinal obstruction following gangrenous appendicitis and who also had fæcal fistulæ. A macrocytic anæmia with normal gastric analysis developed. The anastomoses were undone and the diarrhœa ceased, but further treatment of the macrocytic anæmia with liver was necessary. On two occasions withdrawal of treatment was followed by relapse, and on the second of these the patient developed "combined system disease" and died; necropsy showed obstruction from adhesions.

The second, a patient of Hurst (1933), was a woman aged 30 with symptoms of intestinal obstruction following appendicectomy. She was treated by ileocolic anastomosis, and five years later she developed severe macrocytic anæmia with free acid in the gastric juice and signs of further obstruction. She had bilateral extensor plantar responses and diminished knee-jerks and ankle-jerks, with pins and needles in feet and hands. She died three weeks after operation for relief of the obstruction. There is no mention of a necropsy.

Woltman and Heck (1937), reviewing degeneration of the spinal cord in conditions other than pernicious anæmia, gave details of a woman aged 60 who developed multiple intestinal fistulæ and a fæcal fistula after appendicectomy. Later the hæmatological and neurological picture of pernicious anæmia developed, and typical subacute combined degeneration of the cord was verified at necropsy. There is no mention of any gastric analysis; therefore the concurrent development of true Addisonian anæmia cannot be entirely excluded.

Of 8 patients with short-circuits and intestinal loops were deficient in vitamin $B_{12}$ and hence potential candidates for degeneration of the spinal cord (D. L. Mollin, personal communication). Thomson (1953) describes a man aged 20 with ileocolic anastomosis following appendicitis and macrocytic anæmia but no neurological involvement. The anæmia was cured with vitamin $B_{12}$, and, later, operation to restore normal bowel continuity made further treatment with vitamin $B_{12}$ unnecessary. In an analysis of the "intestinal loop syndrome" Jackson and Linder (1951) conclude that involvement of the upper end of the small gut tends to produce predominantly steatorrhœa, and of the lower end predominantly anæmia. From the present review it seems that neurological complications, when they occur, are also commonest with lesions of the lower part of the small intestine.

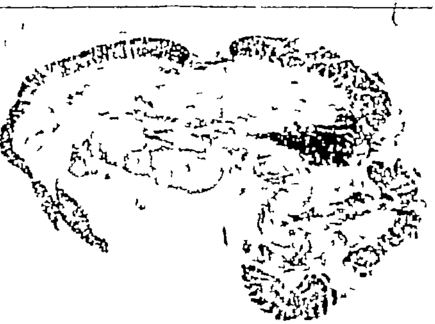

Fig. 2—Section through fistula, showing absence of Crohn's disease and of tuberculosis. (× 8.)

The ætiology of the fistula in the present case remains obscure. Taylor (1930) found at necropsy of a woman aged 54 with macrocytic anæmia and multiple intestinal diverticula the peritoneal cavity almost obliterated by adhesions, as in the present case, presumably due to past inflammation. Perforation of one of the small-bowel diverticula into the colon seems the most likely cause of the fistula in the present case. There was no histological evidence of Crohn's disease or of tuberculosis (fig. 2).

## Summary

A case of subacute combined degeneration of the spinal cord with macrocytic anæmia following the development of an ileocolic fistula of unknown cause is reported.

The fistula was demonstrated by a barium meal but not by an opaque enema.

The anæmia and the spinal-cord disease were arrested by treatment with liver extract. Resection of the fistula completed the cure, doing away with the need for further liver injections.

Three years after operation the patient is well and has a normal blood count.

I wish to thank Dr. H. S. Kellett for the hæmatological findings, Dr. R. J. C. Campbell for the radiograph, and Dr. R. E. Steiner for advice and encouragement.

# PAPAIN-TREATED RED CELLS IN THE DETECTION OF INCOMPLETE ANTIBODIES

K Goldsmith
M B Lond
PATHOLOGICAL REGISTRAR WESTMINSTER HOSPITAL, LONDON

PROTEOLYTIC enzymes modify red cells so that they can be agglutinated in saline suspension by incomplete rhesus antibodies Following work with cholera filtrate by Pickles (1946) Morton and Pickles (1947) described the use of trypsin for the purpose and later (Morton and Pickles 1951) described the use of a filtrate of *Streptomyces albus* extract and briefly mentioned tests using papain Kuhns and Bailey (1950) reported on papain more fully The technique described below, modified from that of Kuhns and Bailey, has proved both reliable and delicate Stratton (1953) introduced a slide technique using papain treated red cells The method he recommended was used in parallel with the tube technique in the examination of 110 sera

The use of papain treated cells obviates certain objections to other methods of detecting antibody prozone effects, the formation of rouleaux in protein and other colloidal media, the expense of commercial bovine albumin, and the time and skill needed to produce the anti-human globulin serum of Coombs et al (1945)

## Reagents

*Stock Papain*—1 g of papain is suspended in 100 ml of 0 85% sodium chloride It may be stored for several months at +4°C Eleven brands of papain were tested All appeared reliable, but those of Biddle, Sawyer * and of Mawson † appeared the most active for the purpose

*Preparation of Papain Solution*—As an alternative to the papain suspension described above a more elegant preparation in the form of a solution may be obtained as follows Stock papain suspension is stored at +4°C for twenty four hours care being taken to agitate it at intervals It is then centrifuged, and the supernatant fluid is retained for use in exactly the same way as the suspension The solution is slightly less active than the suspension but has proved wholly reliable

*Storage of Stock Papain for Long Periods*—Whereas stock papain in current use keeps best at +4°C, thus eliminating the need for constant freezing and thawing, the stock reagent will keep for long periods at −20°C It has been found useful to store at −20°C the bulk stock papain, be it suspension or solution A small quantity at a time is thawed out and kept at +4°C for routine use

*Stock Buffered Saline Solution*—1 volume of 1/15 molar Sorenson phosphate buffer, pH 7 3, prepared by adding 3 parts $M/15$ $Na_2HPO_4$ to 1 part $M/15$ $KH_2PO_4$, is added to 9 volumes of 0 85% sodium chloride solution

*Red Cells for Treatment*—Red cells, both group O rhesus positive (CDe/cDE, $R_1R_2$) and group O rhesus negative (cde/cde,rr) are washed three times in 0 85% sodium chloride solution After the last washing they are packed

## Method

Nine volumes of stock buffered saline solution are added to one volume of stock papain To one volume of the thrice-washed packed rhesus-positive cells and to one volume of the thrice washed packed rhesus negative cells are added in each case two volumes of the buffered saline papain mixture The cell suspensions so prepared are incubated for thirty minutes at 37°C in a water-bath The cells are next washed three times and made up to a 5% concentration in 0 85% saline solution Before use they are warmed to 37°C

0 1 ml of the serum to be tested is pipetted into each of two "precipitin" tubes (7 × 50 mm) and warmed to 37°C in the water-bath This eliminates the non specific agglutination shown by many sera of enzyme-treated red cells at +20°C or less 0 1 ml of the enzym treated rhesus positive cell suspension is added to o of the two precipitin tubes, and a similar quantity o the rhesus-negative cells to the other After an hour incubation at 37°C the two tubes are read macrosco cally and checked microscopically for the presence o agglutination, care being taken not to let the red ce cool during the process Microscope slides warmed t 37°C may be used to lessen the degree of false posi results due to cold agglutinins

## Results

61 sera containing rhesus antibody were ex On no occasion was macroscopical agglutination abse In each case a papain treated red cell titration was do and parallel titrations were done with red cells suspende in saline solution and in 20% bovine albumin, and b the anti-globulin technique of Coombs et al (1945) a the trypsin and *Strep albus* techniques of Morton an Pickles (1951)

110 maternal sera were examined by Stratton's technique in parallel with the papain method describe above and with the other methods mentioned 5 specimens gave a false positive result by Stratton's method all other methods used in parallel being negative Th technique, when antibody titrations were compared seemed to be as sensitive as the tube papain te described in this paper

The tube technique with papain-treated red ce proved as sensitive as any other method, giving ve few false positive results The table gives examples results obtained with four typical anti Rh sera

EXAMPLES OF TITRATION OF FOUR RHESUS ANTISERA

| — | Rhesus antiserum | | | |
|---|---|---|---|---|
| | 1 | 2 | 3 | 4 |
| Saline solution | 0 | 0 | 1 | 0 |
| 20 % bovine albumin | 2 | 8 | 2 | 1 |
| Anti globulin test (Coombs et al 1945) | 2 | 8 | 8 | 3 |
| Trypsin technique (Morton and Pickles 1951) | 4 | 32 | 16 | 6 |
| *Strep albus* technique (Morton and Pickles 1951) | 4 | 64 | 16 | 6 |
| Papain technique (tube method) | 8 | 512 | 16 | 1 |
| Papain technique (Stratton 1953) | 8 | 256 | 16 | 1 |

In 3370 maternal sera examined papain gave o 11 false positive results and no false negatives It believed that most false positive results develop a result of cooling of the cell serum mixture Of the fa positives only one was detected on repeating the t again with the same reagents During tests with papa treated red cells in other blood group systems enhanc ment of agglutination was noted with Anti-A, Anti Anti M, Anti N, Anti $Le^a$, and Anti $Le^b$ No agglutinati took place with Anti $Fy^a$

## Discussion

The method described has certain advantages o *other antibody techniques in routine use The format* of rouleaux, common in protein media, is obviat Papain is much more economical than the relativ expensive commercial bovine albumin Moreover t considerable time and skill required for the p of anti-human globulin used in the Coombs techni is avoided Papain appears more sensitive than eit trypsin or *Strep albus* The method described is simp than that of Kuhns and Bailey (1950), for they rec mend continual agitation of the cell suspension dur the time that it is being treated with the enzyme, a suggest centrifuging the tubes containing cell s mixture before finally reading the results Both th requirements have been eliminated

---

* Biddle Sawyer 1 Grafton Street London W 1
† Mawson c o John Bell & Croyden 50 Wigmore Street, London

In Stratton's method it is necessary to prepare an activator fresh on the day of use. This was also found unnecessary moreover the error due to false positives was rather higher than in the tube method.

## Summary

A method is described for the preparation and use of papain treated red cells to detect incomplete rhesus antibody.

Results of testing 3370 maternal sera are considered as well as the titration of 61 rhesus antibodies. Mention is made of reactions with papain treated red cells in other blood group systems.

The papain technique appears very reliable and more sensitive than any other for routine use in the detection of incomplete rhesus antibodies.

Thanks are due to Prof R J V Pulvertaft Dr A E Mourant and Dr J G Humble for very helpful advice and criticism and to Dr Mourant for the various antisera.

# PRIMARY PEPTIC ULCERATION OF THE JEJUNUM

S LEVITT
M.B Adelaide
RESIDENT MEDICAL OFFICER

ERIC G SAINT
B Sc M.D Durh M.R.A.C.P
DIRECTOR OF CLINICAL RESEARCH

ROYAL PERTH HOSPITAL PERTH, WESTERN AUSTRALIA

WHEREAS *ulceration of the jejunum* as a sequel to gastro-enterostomy is so common as to bring that operation for the treatment of duodenal ulcer with hyperchlorhydria into universal disfavour primary jejunal ulceration is distinctly uncommon.

The first description of *primary jejunal ulceration* was attributed by Ebeling (1933) to Sostier (1827). Richardson (1922) reviewed 12 published cases and added 1 of his own; Ravdin (1927) brought the tally up to 23; and Ebeling (1933) reviewed 47 cases. Berry and Dailey (1940) brought to light 9 other published cases which had been missed; and these, their own case, other cases subsequently published (Robinson and Wise 1940, Dowdle 1942, Chambers 1943, Carmichael and Doggett 1946, Evert et al. 1948) and the present case bring the total number of published cases to 83.

Primary jejunal ulcers behave in every respect like peptic ulcers of the lesser curvature of the stomach or the first part of the duodenum inasmuch as they may cause symptoms of dyspepsia and may bleed, perforate, or stenose. Both the practical considerations of natural history and management and the theoretical consideration of ætiology of primary jejunal ulceration are well illustrated in the ensuing case.

## Case report

A married woman aged 23 first began to complain of ulcer pain in 1951. She had previously been healthy if rather delicate. The only relevant past history was of amenorrhœa associated with an infantile uterus and attributed to ovarian insufficiency. In January 1951 she complained of epigastric pain and heartburn coming on two or three hours after a meal and relieved by food and alkalis. In February 1951 when she presented herself as a blood-donor she was rejected on the score of anæmia.

Early in 1952 she became weak and noticeably more pale and her attention was drawn for the first time to the passage of tarry stools. Her dyspeptic symptoms had meanwhile subsided but in February 1952 she had an attack of severe upper abdominal pain lasting three days. Her hæmoglobin was only 5 g per 100 ml and she was given blood transfusions. Barium meal radiography at that time is said to have indicated a possible ulcer in the second part of the duodenum (fig 1) but a further radiograph taken two weeks later did not confirm this finding. During the ensuing three months she continued to have intermittent upper abdominal pain.

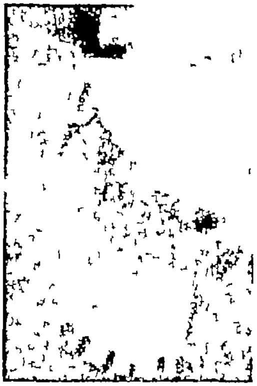

Fig. 1—Barium-meal radiograph in January 1952 showing apparent ulcer crater in second part of duodenum. This crater was not seen in barium-meal radiograph two weeks later.

*First Admission and Laparotomy.*—In May 1952 she was admitted to the Royal Perth Hospital after a very severe attack of melæna. She was a thin frail girl of considerable intelligence but displaying a child-like dependence on her dominating mother. Physical examination was unrevealing. The abdomen was lax and not tender. A fractional test meal showed an exceptionally high level of acid secretion, free HCl rising to 100 clinical units at the end of the first hour without histamine stimulation. Barium meal radiography (fig 2) showed some distension of the duodenum and jejunum, the significance of which was unapparent. The proximal jejunum did not show active peristalsis.

Laparotomy confirmed the duodenal dilatation but no bowel lesion was detected and no active surgical measures were undertaken.

*Second Admission.*—In September 1952 further upper abdominal pain was followed by a severe hæmatemesis. No abnormality of the stomach was disclosed at gastroscopy.

*Third Admission.*—Early in 1953 the patient complained again of epigastric pain occurring two hours after meals and radiating into the back. The pain was not now relieved by food or by alkalis. After another attack of melæna she was readmitted and given blood transfusions. Barium meal radiography and gastroscopy were unrevealing and a cholecystogram was normal. Overnight gastric secretion, followed by a histamine test meal in the morning, was studied. The results are shown in figs. 3 and 4. Total nocturnal secretion of gastric juice and HCl production exceeded even the mean values obtained by Levin et al (1952) in male patients with duodenal ulcers. Before this admission the patient had also complained of loose motions passing two or three bulky pale offensive stools daily. The suspicion of steatorrhœa was not confirmed for on a daily intake of 160 g of fat 90% was absorbed.

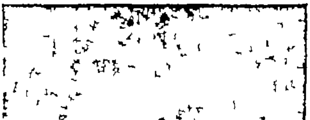

Fig 2—Barium-meal radiograph in May 1952, showing considerable dilatation of second and third part of duodenum

*Fourth Admission and Second Laparotomy.*—Further pain

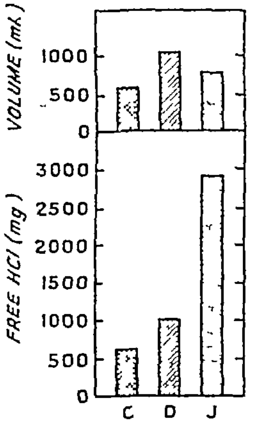

Fig 3—Volume of and amount of free HCl in gastric juice secreted from 9 p m to 9 a.m by controls (C), male patients with duodenal ulcer (D) (Levin et al 1952), and patient with primary jejunal ulcer (J)

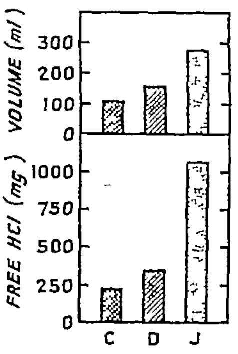

Fig 4—Volume of and amount of free HCl in gastric juice secreted in 1 hr after histamine stimulation in controls (C), male patients with duodenal ulcer (D) (Levin et al 1952), and patient with primary jejunal ulcer (J)

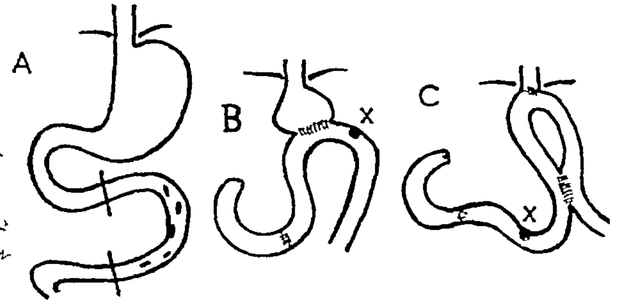
and hæmatemesis occurred in October 1953 Gastroscopic appearances of the stomach were again normal Several hours after gastroscopy the patient complained of acute generalised abdominal pain Examination showed distension and abdominal rigidity The radiological demonstration of gas under the diaphragm confirmed the diagnosis of perforation of the bowel

At laparotomy (Mr Hector Stewart) a perforation of the jejunum on its antimesenteric border about 10 cm distal to the duodenojejunal flexure was found The edges felt indurated, suggesting perforation at the site of the ulcer What was thought to be another ulcer was palpated about 6 cm proximal to the site of perforation The stomach was normal The duodenum was greatly dilated The ulcer was oversewn, and the abdomen was closed without drainage

*Fifth Admission and Third Laparotomy*—In December 1953, the patient was readmitted for elective resection of the proximal jejunum (Mr Stewart) The duodenojejunal flexure was mobilised and about 40 cm of the ulcer bearing proximal jejunum was resected with end to end duodenojejunal anastomosis With a more distal loop of jejunum a classical Polya subtotal gastrectomy was then done (fig 5A and B) The postoperative course was uncomplicated

*Sixth Admission and Fourth and Fifth Laparotomies*—In January, 1954, two days after discharge, the patient returned complaining of severe upper abdominal pain She was febrile, with a white cell count of 17,000 per c mm An indefinable mass was felt in the left upper abdominal quadrant, and an intraperitoneal collection of pus was diagnosed Before exploration could be contemplated two further hæmatemeses occurred At gastroscopy the stoma was well visualised, but no ulcer was seen The volume of aspirated fasting gastric juice was 70 ml containing 24 units of free HCl

At exploration it was seen that perforation of another ulcer, about 1 5 cm in diameter and situated 2 cm distal to the stoma of the gastrojejunostomy, in the efferent loop, had led to the formation of a large abscess walled off by coils of intestine and omentum To oversew this ulcer was technically impossible, the most that could be done was to plug it with omentum The gastrojejunostomy was unpicked and the jejunum repaired The remainder of the stomach was excised and a loop of jejunum well distal to the ulcer was anastomosed to the œsophagus, with side to side jejunojejunostomy (fig 5C)



Fi sites of jejunal ulcers B, anatomical result following jejun with duodenojejunostomy and subtotal gastrectomy C, tomical result (total gastrectomy) X site of postoperative and perforation

The postoperative course was stormy, with paralytic ileus and bilateral pleural effusion as complications After two weeks a mounting temperature and white cell count, with a palpable mass in the left loin, indicated a further collection of pus Exploration revealed a large left-sided retroperitoneal abscess which was drained The patient made an uninterrupted recovery

*Pathology*—The specimen obtained at the time of subtotal gastrectomy consisted of 40 cm of proximal jejunum, including its mesentery, which contained several enlarged lymph nodes The lumen of the jejunum was narrowed to the diameter of a lead pencil opposite the site of the ulcer, which had previously been oversewn Six ulcers, varying in diameter from 0 5 to 1 5 cm, scattered haphazardly round the circumference of the bowel, were present in the proximal 20 cm of the jejunum Both macroscopically and microscopically (fig 6) the ulcers had the appearances of peptic ulcers of other sites The surrounding jejunal mucosa was normal Heterotopic gastric mucosa was not present in serial sections Chronic inflammation alone seen in the mesenteric lymph nodes

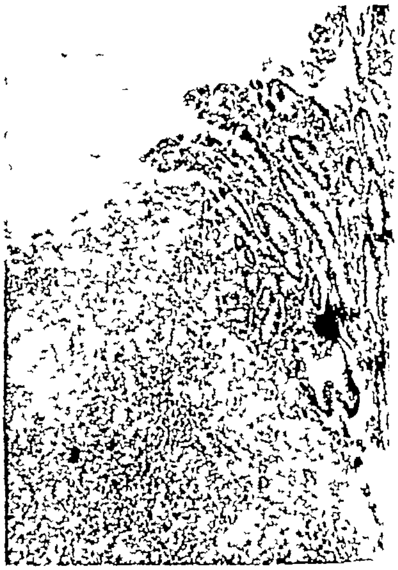


Fig 6—Section of edge of one of six ulcers resected portion of proximal jejunum Part sloughing fibrinous base is in left-hand of field

## Discussion

At the time of Ebeling's (1933) review the mortality rate from primary jejunal ulceration with perforation was 68 5% Notwithstanding subsequent improvements in surgical and related techniques the patient is indeed fortunate in having survived so many hazardous complications

The distribution by age and sex of primary jejunal ulceration is strikingly similar to that of duodenal ulcer Among those affected the ratio of males to females 3 5 to 1, and symptoms and complications usually occur in the fourth, fifth, and sixth decades of life The range of age distribution, however, is great, a child aged years being the youngest patient recorded (Kirmisson 1898) and a man aged 77 the oldest (Velter 1924) So far as can be ascertained, our patient is the youngest female on record

The repeated inability to demonstrate a lesion either radiologically or gastroscopically to explain the obvious symptoms of peptic ulceration was a source of perplexity for two years In retrospect, the constantly seen dilatation of the duodenum and the absence of peristalsis in the jejunum in barium studies was of diagnostic significance Even if ulcers in the jejunum are not radiologically demonstrable, it seems that a diagnosis can be tentatively made, before dangerous complications develop, on t basis of a history of ulcer pain and the radiological demonstration of abnormalities of muscular tone in he duodenum and jejunum A study of radiological findings in previously reported cases supports this view

The nearer the ulcers lie to the duodenojejunal flexure he closer do the symptoms simulate those of duodenal ulcer The periodicity of pain, its relation to meals and he relief obtained from acid neutralising agents were all characteristic of duodenal ulcer pain and suggest a similar mode of origin (Bonney and Pickering 1946) Later the component of abdominal colic was added to the underlying dyspeptic pattern suggesting abnormal peristaltic activity proximal to the sites of ulceration As in more proximal peptic ulcers bleeding was invariably followed by temporary relief of pain

Of the various complications common to all peptic ulcers perforation has occurred in about 80% of all cases of primary jejunal ulceration In a large number of cases it has been the mode of presentation Preceding trauma has often been implicated indeed with deep seated ulceration of so thin walled a viscus it is not surprising that sudden alteration of intra abdominal tension may be a precipitating influence In a case of medicolegal interest the *British Medical Journal* (1906) reported that a jejunal ulcer was fatally perforated by a blow on the abdomen

The occasion afforded the coroner the opportunity of pillorying a member of the (medical) profession and various newspapers some striking headlines.

Recurrent hæmatemesis and melæna the outstanding diagnostic problem of our case are much less common we know of only 2 published cases (Schmilinski 1910 Murphy 1916) Stenosis of the jejunum has been described by Ebeling (1933)

We have consistently referred to primary jejunal ulcers as peptic ulcers for on clinical and pathological grounds there seems very good reason to do so Histologically their appearances are indistinguishable from hose complicating gastro enterostomy and from chronic gastric and duodenal ulcers indeed 2 cases have been published of the association of primary jejunal ulcers with ulcers in more proximal sites with chronic gastric ulcer (Barber 1926) and with duodenal ulcer (Murphy 1916)

The quite phenomenally high level of acid secretion in his patient was of obvious ætiological importance Even conventional subtotal gastrectomy failed to reduce otal acid secretion sufficiently to prevent the development of further jejunal ulceration Although pH gradients were regrettably not studied it is reasonable to assume that even in the presence of normal pancreatic and bile secretion the pH of jejunal contents during interdigestive phases was considerably lower than normal The susceptibility of jejunal mucosa to acid peptic ulceration is well known What is of great interest s the negative observation that in the presence of such an abnormal degree of hyperchlorhydria the patient did *not* have a duodenal ulcer In the genesis of duodenal ulcer it is clear that two factors are involved: the level of gastric acidity and factor X the inherent susceptibility to ulceration of the duodenal mucosa The elucidation of factor X which may be due to local reflex ischæmia or to a defect in the local mucous protecting barrier Hollander 1954) remains one of the most outstanding problems in the study of peptic ulcer

After having been a surgical curiosity it is possible hat the patient will eventually provide a hæmatological case report for the total removal of the stomach and a large part of the jejunum in a female so young is almost bound to lead to deficient absorption of both iron and vitamin $B_{12}$ From the point of view of deficient absorption of iron it is perhaps fortunate that owing to hypo ovarian function she has no menstrual blood loss

## Summary and Conclusions

The case is reported of a young woman who presented with symptoms of ulcer pain and in two years had at least five severe episodes of melæna due to primary ulceration of the jejunum The diagnosis was made at laparotomy undertaken for perforation of the bowel When recurrence of ulceration with further perforation and hæmatemesis followed subtotal gastrectomy, it was considered necessary to remove the remainder of the stomach

Primary jejunal ulceration must be considered in patients with a history of ulcer pain whose stomach and duodenum appear normal on barium meal radiography Suggestive radiological signs are dilatation of the distal duodenum and jejunum with diminished peristaltic activity

Perforation has been a common and hazardous complication of primary jejunal ulceration

Treatment consists in excision of the affected jejunum If preoperative studies reveal normal secretion of gastric HCl subtotal gastrectomy in addition will probably suffice but if severe hyperchlorhydria is present total gastrectomy must be considered

We are extremely grateful to Mr Hector Stewart and Dr Gerald Moss for permission to cite records of the case whilst she was under their care and Mr R Van Raalte for the photographs

# PROLONGED ANURIA TREATED BY INFUSION INTO THE VENA CAVA

J A Chalmers
M.D Edin., F R C.S E. F R C O G
CONSULTING OBSTETRICIAN AND GYNÆCOLOGIST
RONKSWOOD HOSPITAL, WORCESTER

H T Fawns
M.Sc Lond. M R C.S F R I C
BIOCHEMIST DEPARTMENT OF PATHOLOGY ROYAL INFIRMARY
WORCESTER

The management of prolonged anuria by continuous infusion into the vena cava was recently described by Russell et al (1954) The following case further illustrates the use of this method in conjunction with biochemical control of electrolytes

## Clinical Record

Mrs S aged 44 was admitted to hospital on April 19 1954 for repair of a prolapse A Manchester operation was carried out on April 21 but because the patient was anæmic she was given an intravenous transfusion of one pint of group O rhesus negative blood before operation During the operation there was considerable bleeding and it was decided to continue the transfusion Blood had previously been cross matched for her and was held in the hospital laboratory but through an error the blood which was sent to the operating theatre was for another patient of similar name who was also for operation that afternoon This blood was group A rhesus p and the mistake was unfortunately not discov 300 ml had been administered

*Management*

Twelve hours later the patient had secreted only 1 oz. of urine, so the Bull régime of dextrose and peanut oil by intragastric drip was begun (Bull et al 1949) During the next eight days the urinary output remained very low, as little as ½ oz being collected in twenty four hours (fig 1) Vomiting was troublesome from the second day, and on April 29, when her blood urea had reached 361 mg per 100 ml , she began to have profuse diarrhœa 23 oz of fluid was lost from the bowel on April 29, 85 oz on the following day, and 24 oz on the morning of May 1

The timely appearance on this very day of the paper by Russell et al (1954) prompted us to revise our plan of treatment The patient was becoming extremely dehydrated and the alimentary tract apparently no longer afforded a satisfactory avenue for hydration and nutrition Since further diarrhœa would probably have led to extreme dehydration and death, at midday on May 1 the Bull régime was discontinued and an infusion was begun through a ' Polythene ' catheter passed up the saphenous and femoral veins of the right thigh into the vena cava This was maintained for eleven days, and during this time the urinary output rose steadily to 107 oz on May 11, when the infusion was continued We had intended to leave it longer, but the of a sacral bedsore made this impracticable

The constitution of the infusion (see table) was daily to give an adequate fluid intake, to maintain a reas alkali reserve, to ensure a sufficient calorie intake, achieve a balance of sodium and potassium To thrombophlebitis, 15,000 units of heparin was to the 40% glucose solution Heparin was not added less concentrated solutions Estimations of the time were made to ensure that the dosage was not exc Vitamins in the form of ' Becosym ' (Roche) 1 ampoule ascorbic acid 100 mg , were given daily by intramus injection from May 3 until the patient returned to fu

*Progress*

From May 11 the patient was given fluids by mouth, on May 14 light diet was begun Although the urinary continued to increase—indeed it reached a figure of on May 28—the concentrating power of the kidney this period remained seriously impaired, and the urea-c was therefore considerably diminished (fig 1) This

mixture consisted of M/6 sodium lactate (4 fl oz ) potassium chloride (gr 7½), sodium chloride (gr 22½ ) lactose (gr with fruit juice (10 fl oz )

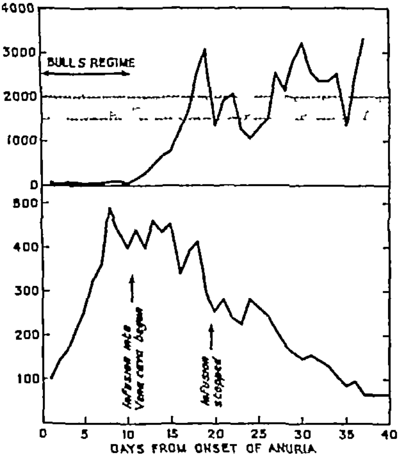

Fig 1—Relationship between urinary output and blood-urea.

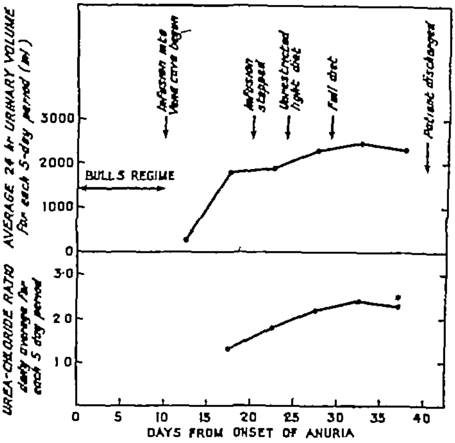

Fig 2—Rise in the urea-chloride ratio which accompanied the increased output. Three-day average ratio

oved however and with the administration of adequate the blood urea level gradually fell, and on the patient s arge from hospital on June 2 it was only 67 mg per ml Three weeks later it had fallen to 51 mg per 100 ml he urea-clearance remained only 36% of normal A month the blood urea was 42 mg per 100 ml and the urea ance had risen to 48% of normal The most recent test ed out on Sept 29 (162 days after the onset of the anuria) ed a blood urea of 35 mg per 100 ml and a urea-clearance of normal Further improvement in the renal function is dently expected

e patient's gynæcological condition remained satisfactory ghout, and the repair of the prolapse appears to have been ssful The patient s general condition is now good and ally she appears normal

BIOCHEMICAL INVESTIGATIONS

*ytical Methods*

ood urea was estimated by the colorimetric micro method ober and Robb described by King (1951) urinary urea ho hypobromite method Serum proteins were estimated he biuret method of Wolfson et al. (1948) Plasma ide was estimated either by the method described by (1951) or direct in the plasma without deproteinisation he rapid method of Schales and Schales (1941); direct tion with silver nitrate using potassium chromate ator was employed for its estimation in urine vomit and s. Sodium and potassium were estimated throughout on EL flame photometer Carbon-dioxide combining power determined by the Van Slyke method

*lts*

or the first nine days of treatment before the start of the sion into the vena cava only the blood urea was estimated its level rose steeply as the period of anuria lengthened 1) From the tenth day of anuria when the infusion the vena cava was begun detailed analyses were made lood urine vomit and of the one specimen of liquid s passed (see table) The blood constituents mentioned o were estimated daily until the twenty third day—i.e *s days after the intracaval infusion was stopped By then* blood urea level had dropped to approximately half its value and the over all biochemical picture was much e satisfactory Clinically the patient was improving but her veins had suffered from the repeated vene tures It was therefore decided to discontinue the daily d-chemistry investigations except for blood-urea and oglobin estimations which could be done on samples ined by finger prick A final complete examination was ied out on the twenty-eighth day

he urine was examined daily for twenty four hour volume specific gravity Chlorides sodium, and potassium were estimated with a view to making good the daily loss of these constituents; and the daily output of urea was also determined These procedures were also continued until the time of the patient s discharge The results obtained from analysis of urine vomit and liquid stool for the thirteen days of detailed investigation following the setting up of the infusion into the vena cava are set out in the table, below the corresponding results obtained from blood analysis.

The daily urine volumes up to the time of the patient s discharge, together with the values for blood urea are shown in fig 1 The diuresis which rapidly followed the start of the infusion was accompanied by a significant drop in the blood urea level Although subject to rather large daily fluctuations, the flow of urine continued to be satisfactory after the polythene catheter was removed and oral fluids were begun The blood urea, which was 440 mg per 100 ml immediately after insertion of the catheter had fallen to 252 mg at the time of its removal and to 63 mg at the time of the patient s discharge

The urine was of low specific gravity throughout (1 003-1·012) The usual value was 1·006–1 009 and varied approximately in inverse relation to the volume The urea concentration was consistently low and varied with the specific gravity The highest value recorded was 1 12 mg per 100 ml (usually it lay between 0 7 and 0 9 mg per 100 ml); which suggests that during the initial period of renal recovery the concentrating power of the kidney was poor and elimination of urea was effected mainly by an increase in the urinary volume A large urinary output was encouraged by allowing the patient who was very thirsty to drink fluids ad lib Muirhead et al (1948) in their study of a series of similar cases, showed that an increase in the urea/chloride ratio took place concurrently with recovery and they suggested that this might be of prognostic value The urea chloride ratio was therefore determined daily and was found to rise steadily—a point brought out more clearly when the five-day averages were plotted (fig 2) The rise is proportionate to the increase in the average twenty four hour urinary volume for each five-day period

## Discussion

This case demonstrates firstly how very easy it is despite routine precautions to give an incompatible blood transfusion to an unconscious patient To prevent a recurrence of this, blood is now issued from our hospital laboratory only on receipt of a written requisition bearing the patient s full name age and registration number Only the timely appearance of the paper by Professor Russell and his colleagues enabled us to avoid a fatal outcome since the copious diarrhœa made the Bull regime ineffective At the start of the extensive biochemical investigations one of the most dangerous features of this case was severe acidosis The infusion into the vena cava enabled prompt rectification of the acidosis with $M/6$ sodium lactate, as well as rapid correction of dehydration resulting from the diarrhœa, which would not have been possible with a peripheral venous infusion

In the management of this case several minor points arose which are worth mentioning

(1) It is inadvisable to use the intravenous catheter to obtain samples of blood for analysis since the procedure may disturb it as well as increase the risk of sepsis It may, however be used to obtain essential samples of blood if no peripheral vein is available

(2) Prophylactic procaine penicillin (1,000,000 *units daily*) was begun on May 1 but was discontinued after three days because an urticarial rash developed In spite of daily bladder lavage, the urine subsequently became infected with *Staphylococcus pyogenes*, but the infection was successfully treated with a course of erythromycin

(3) In order to prevent displacement of the catheter it was necessary to limit the patient's movements, which resulted in the development of a bed sore This healed rapidly with routine treatment once the catheter had been removed and the patient's mobility restored

(4) In view of the risks attendant upon intravenous potassium therapy, a low serum potassium level was disregarded until potassium chloride could be administered cautiously by mouth

(5) When the time came to start feeding the patient orally, lactose was chosen in preference to glucose, since it is less sickly and therefore less likely to cause vom
at that stage, might have been dangerous

## Summary

A case of prolonged anuria due to incomp
transfusion is recorded

After ten days on the Bull intragastric
diarrhœa supervened of such severity as to r
treatment by this method ineffective

Infusion into the vena cava was substit
next ten days, and this made possible ex
chemical control of fluids and electrolytes u
began

By using a 40% glucose solution in the inf
possible to supply sufficient calories in a m
volume of fluid

## ROYAL SOCIETY OF MEDICINE

### Anæmia in General Practice

THE section of general practice met on Dec 15, with Dr R J Minnitt, the president, in the chair, to discuss the Management of Anæmia in General Practice

Dr Douglas French described the incidence of different types of anæmia in his practice of some 5000 patients Patients with iron deficiency anæmia averaged 80 a year, half of these cases were associated with pregnancy In eleven years he had seen only 13 patients with pernicious anæmia, 2 with chronic myeloid leukæmia, 1 with acute leukæmia, and altogether 10 with the rare types of blood-diseases, he had 4 hæmophiliacs in his practice, 3 of them in one family These figures meant that, judging by his experience the general practitioner had to deal almost exclusively with iron deficiency anæmia, other types were relatively rare and needed hospital investigation for proper diagnosis It followed that vitamin $B_{12}$, folic acid, liver extracts, or mixtures containing these substances were rarely needed, and they should in fact never be used unless there was a clear therapeutic indication for them Dr French did blood counts—red cells, hæmoglobin, white cells (total and differential)—on all anæmic patients Anæmia was rarely very urgent, and it paid to spend a few days on correct diagnosis rather than start treatment which might prove after some weeks to be incorrect The colour index was a useful guide to sorting cases, if it is over 1 0, the patient should be sent to hospital and no treatment should be given If the colour index was about 1 0 iron deficiency anæmia was the most likely diagnosis, so treatment with iron was given, but the patient was sent to hospital if the response was not up to expectations It was important to regard iron deficiency as a physical sign, not as a diagnosis per se a cause for the anæmia must be sought —in particular, tuberculosis peptic ulcer, complications of pregnancy malignant disease rheumatoid arthritis, and bleeding hæmorrhoids must be considered

In treating the anæmia, "an air of expectant scepticism" be maintained, and one should be careful not to spoil clues for subsequent specialist examinat
should be needed Oral iron should give a
rise of 1% (0 148 g per 100 ml) per day
difference was found between inorganic sal
ferrous sulphate, and organic salts, such
succinate Intravenous iron gave a rather
rise, and Dr French used this preparation
patients with an initial hæmoglobin of less
(9 g per 100 ml), (2) all patients with h
anæmias of pregnancy, (3) the minority of p
genuinely failed to respond to oral iron,
cases in which the diagnosis was in doubt
injections were given daily if possible, since t
patient interested, and the course was quickly
The dose used was 25 mg Fe per 1% hæmoglo
and this sufficed, he found, to give a reticulo
8–10% on the fifth to eighth day If intra
did not restore the blood picture to norm
important to look for chronic blood loss an
diseases already mentioned

In pregnancy the presence of hydræmi
remembered, Dr French suggested from
observations that a red cell count of 4,000,00
and hæmoglobin of 80% (12 g per 100 r
twentieth week was normal He pointed out th
a physiological rise of hæmoglobin on the da
a fall on the first three days of the puerperium,
gradual recovery to normal levels in the next
these normal variations tended to be forg
assessing the value of iron preparations in
anæmia In the true iron deficiency anæmia of
intravenous iron was the most effective treat

Dr M C G Israëls agreed that the c
provided a useful guide to the practitioner's
action and he pointed out that almost all t
whose anæmia was not due to iron deficiency
least outpatient hospital investigation for pr
ential diagnosis A colour index about 1
malignancy (especially of the alimentary tra
loses (including Hodgkin's disease), or ur
some of these patients proved to have pri
deficiency anæmia A colour index over 1
quite a different group of diseases pernicio

ukæmia (especially the aleukæmic forms), acquired æmolytic anæmia sprue and non tropical steatorrhœa nd aplastic anæmia Dr Israëls dealt with the differ ntial diagnosis of these conditions and pointed out how uportant it was *not* to give vitamin $B_{12}$ folic acid or ver or any of the so called complete hæmatinics to hese patients before the diagnosis was settled since hese substances were liable to confuse the diagnostically ritical examination of the bone marrow He emphasised hat the various hyperchromic anæmias all needed quite ifferent treatment

In pregnancy the physiological hydræmia meant that eliance could not be placed on the colour index which ught often be over 1 0 without there being a megalo lastic change in the marrow The diagnosis of megalo lastic anæmia of pregnancy could be settled only by one marrow examination and this should certainly be one for every patient whose hæmoglobin level was elow 9 g per 100 ml (70%) and who did not respond o parenteral iron If megaloblastic changes were found reatment with folic acid soon restored the blood picture

Dr CHARLOTTE NAISH asked about anæmia in old ersons which changed from hypochromic to hyper hromic with iron treatment given liver they improved Vas not this a case for the use of the condemned 'blunderbusses'? The answer was definitely No he type of hyperchromic anæmia should be established irst and Dr Israëls drew her attention to the fact that folic acid must not be given to patients with pernicious anæmia

Dr JOHN HUNT said that blood-counting was time consuming for the general practitioner would not a hæmoglobin estimation be enough? Dr FRENCH thought that if the hæmoglobin was less than 85% the red cells should be counted

Dr R M S MCCONAGHEY remarked that it was very important to impress on patients with iron deficiency anæmia that the treatment had to continue for two to three weeks before the patient felt really improved otherwise the patient was liable to become discouraged and stop treatment too soon

Dr J N M CHALMERS mentioned the new intramuscular iron preparations and said that in one case he had seen a rise in hæmoglobin from 35 to 90% with three weeks treatment during which 53 ml of 'Imferon' was given This material gave rise to local discomfort rather more commonly than some reports suggested

Other speakers pointed out that Dr French used a lot of intravenous iron was it really necessary to use it so often in preference to oral iron? Dr FRENCH agreed that it was not really necessary Most patients could tolerate one or other of the many oral iron preparations He had been working on the effects of these intravenous preparations, and they did have the advantage that the doctor could be sure that the patient had received a proper dose

## Clinical Psychiatry

W MAYER-GROSS M.D Heidelberg, F.R C.P director of clinical research, Crichton Royal Mental Hospital Dumfries; ELIOT SLATER M.A M D Camb., F R C.P D P M physician in psychological medicine The National Hospital London MARTIN ROTH M D Lond. M.R.C.P director of clinical research Graylingwell Hospital Chichester London Cassell 1954 Pp 652 50s

THIS is the most considerable textbook on psychiatry et published, or likely to be published for some time, in nglish Its bibliography is far more extensive and international than is usual The legal aspects of psychiatry re reviewed as they affect not only Britain and America ut also France, Germany Scandinavia and other ountries. Mental defect is discussed early affording clear introduction to those many conditions where sychiatric syndromes direct attention to a more primary isorder whether toxic, inflammatory handicapping primarily psychotic In describing the gross or minute ructural lesions which may first present as mental isorder the authors combine sound pathology with spect for psychiatric observation The sections on the pilepsies and cerebral trauma are written in a highly imulating manner and the critical assessment of ucotomy as a treatment for schizophrenic disorders hould convince many that modern psychiatrists are ell aware of both the losses and the gains achieved hrough recent advances in treatment Some will regret hat the descriptions of psychopathic states and neurotic ersonalities have been combined in one large chapter much that these authors write of the history of odern concepts is good that clearer views on the ature of psychopathic states might have been expected them But the chapter as a whole contains many uminating passages the unstable drifter the vagrant id the sexually abnormal are all well described encies is more fully dealt with than usual The authors aim—and back their view with statistics—that the sults of analyses of large groups of patients yield ore trustworthy evidence on the causes of mental sorder than does psycho analysis by Meyerian or reudian methods of small numbers It seems likely hat most criticism of the book will be concerned with is claim Dr Mayer Gross and his colleagues have llowed good precedent in collecting collating and nalysing an abundance of data and much support is fered for their deductions. Psychotherapists who wish to refute these must face the challenge of their carefully collected case-material Some will hope that the authors determinism will be modified by the accumulation of yet more facts

## Chemical Pathways of Metabolism

Vol. II Editor: DAVID M GREENBERG department of physiological chemistry University of California New York: Academic Press 1954 Pp 383 $9.50

THE second volume which completes this treatise follows hard on the first.[1] This time the contributions are all from laboratories in the United States. The first five deal with amino-acid metabolism, and the others are on the purines and pyrimidines, the nucleotides and nucleosides and heme and chlorophyll. They are clearly written with enough structural formulæ to make them easy to follow Those who have not been closely associated with this kind of work will be amazed at the way in which our knowledge of all this intermediary metabolism has been enhanced by the use of radioactive isotopes. How could we ever have found out without them that the C atom lying between the two atoms of nitrogen is derived from formate in the purines but from $CO_2$ in the pyrimidines?

## The Brompton Hospital

*The Story of a Great Adventure* MAURICE DAVIDSON M.A D M Oxfd, F.R C P consulting physician to Brompton Hospital F G ROUVRAY O B E., late house governor Brompton Hospital. London Lloyd Luke, 1954 Pp 152 21s

Brompton Hospital owes its inception to Philip Rose, a solicitor He was impressed by the facts that consumption was the most common and fatal disease destroying a third of the population yet the doors of all hospitals were closed against it His attention had been drawn to the problem when he was unable to obtain hospital treatment for a consumptive clerk employed by his firm

The hospital opened in the Manor House near the Royal Hospital Chelsea on Sept 13 1842 There was accommodation for 20 patients and it is hardly surprising to learn that this was nothing like enough An extension of the house was found to be impracticable and the committee accordingly decided on the more ambitious scheme of erecting a new building to accommodate by successive additions 100 to 200 inpatients The site chosen was at Brompton "a village in Kensington, remarkable for the salubrity of its air and surrounded entirely by nurseries and garden grounds which were amongst the first cultivated in the country " The ground was formerly part of a botanical garden The new building came into use in 1846 and since then the hospital has gone from strength to strength The new wards were ventilated by a forced supply of warmed air, which was held to provide " for the poor a climate nearly approaching that of southern latitudes, the advantages of which can only be enjoyed by the more favoured portion of the community "

---

[1] See *Lancet* 1954 ii 964 1110

There are short biographies of the doctors who have done so much to gain for the hospital its great international reputation—among them Richard Quain, Burdon Sanderson, Douglas Powell, Kingston Fowler, and Percy Kidd The book is intended for lay readers and it will appeal to them, but it will appeal most to those who are proud to have been associated with " Brompton "

### The Biochemistry of Semen

T Mann, M.D , SC D , PH D , F.R S , reader in physiology of animal reproduction, University of Cambridge London Methuen. New York John Wiley 1954 Pp 240 16*s*

As Dr Mann points out in his preface, information on the physiology of semen, and particularly its chemical aspects, is scattered among books and journals, many of which are inaccessible Lack of a comprehensive and up-to-date treatise has handicapped the now numerous biochemists, clinicians, zoologists, and veterinarians concerned with this subject Dr Mann has himself made many important contributions to semen chemistry and physiology since he became especially interested in this subject in 1944, and in this scholarly book he condenses an immense amount of information into a relatively small space The bibliography alone includes nearly a thousand items

He begins with a synopsis of the principal structural and physiological features of spermatozoa and the accessory glands There is a detailed account of the physical and chemical properties of semen—many mammalian, as well as non mammalian species receiving due consideration—and of the methods used for the evaluation of semen quali Next, the influence of extraneous factors—such as hormo sperm egg interacting substances, spermicidal agents, se dilutors, ionising radiation, and deep freezing—is describ Other chapters deal with metabolic processes which sup the spermatozoa with energy for their motility and surviv and special attention is given to seminal fructose (the s which Dr Mann has made peculiarly his own), the occurre of inositol, lipids, citric acid, and nitrogenous bases includ spermine, choline, and ergothioneine, and the pr constituents and enzymes of spermatozoa and se plasma

**Advances in Ophthalmology** (Vol VII–VIII T Hague Uitgeverij Dr W Junk 1954 Pp 758 guilders) —This double volume of *Documenta Ophthalmol* contains the proceedings of the symposium on the re *circulation held in Strasbourg in 1951*, which survey ophth dynomometry in its physiological and clinical implicat The proceedings of a symposium on squint held in 194 by the Dutch Ophthalmological Society while Holland under Nazi occupation are also included Some of the is now out of date, but the account of the *genetic aspects of t* affection by Waardenburg, and the papers on binocular and fusion movement by F P Fischer and J W Wag are both useful The volume also includes monographs Roelofs on optokinetic nystagmus and by Yap Kie Tion experimental keratoplasty

**Heart** (2nd ed Baltimore Williams & Wilkins Londo Baillière, Tindall, & Cox 1954 Pp 680 114*s*) — Aldo Luisada has added two or three short chapters in th new edition of his book and made many changes *to bring t* *text up to date* He continues to classify cardiac *lesions* on anatomical rather than an ætiological basis, a method whic fails to give the correct perspective for such lesions as mit *stenosis* and *constrictive pericarditis* The first chapter those who have made outstanding contributions to cardiol from 1530 to the present day, but no British physicia mentioned after 1912 though two British surgeons are includ The book is well produced on heavy glossy paper, but t price has doubled since the first edition

## New Inventions

### A SMALL URINARY-FISTULA SUCTION-CUP

A URINARY fistula is tedious not only to the patient, whose skin often becomes excoriated, but also to the nurses, who have to keep changing soaked dressings Furthermore large quantities of dressings are required Hamilton Irving introduced his suprapubic apparatus in an attempt to reduce these difficulties, but it was cumbersome and (especially where the patient was obese) it often leaked and caused *pressure sores under* the retaining straps The basic principle of draining the urine into a receptacle without a tube in the fistula was sound, however, and I have therefore used it in designing a suction-cup (fig 1) I describe here This is small and very simple to use and works equally well with little or no attention, whatever the configuration of the patient Being made of ' Perspex ' it should be sterilised by a cold antiseptic solution, and it is fixed over the fistula with strips of ' Elastoplast ' The air inlet is placed uppermost, and the tube, draining from the lowest point, is connected by small-bore pressure-tubing to a Roberts silent suction-pump The patient may [illegible]ept dry both in and out of bed

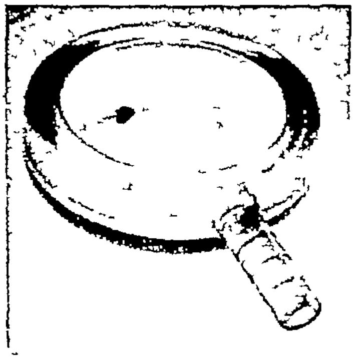

Fig 1

*Although this cup was originally designed for* ur fistulæ it may be used with equal success over fistula draining thin fluid wherever situated Its is adequate for almost every fistula and yet small not to interfere with wound dressings The air inlet (fig 2) allows continuous suction to be used witho creating a partial vacuum and consequent soreness the skin drawn into the cup Furthermore, a curr of air is continuously passing over the skin around fistula, thus preventing it from becoming sodden The inner lip (B) not only prevents urine from seeping between the cup and the skin but also helps the cup to fit more comfortably by increasing the area of contact between the two The connection (C) to which the rubber tube is attached is angled to allow the cup to lie flat even on an obese patient The cup, being made of perspex both light and inexpensive to make

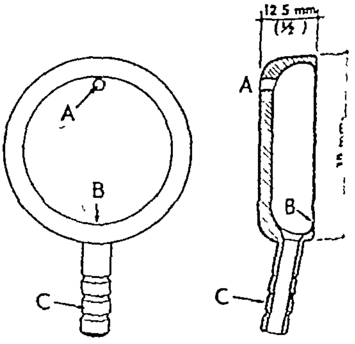

Fig 2.

I am indebted to the Genito Urinary Manufactur Company for making this cup for me from the protot supplied by Mr R A Crispin, to Mr J D Foy for the draw and to Mr F Wardlaw for the photograph This s company also market the Roberts suction pump

## Adrenalectomy for Hypertension

T is more than twenty years since adrenalectomy s first done for the relief of hypertension, and ward of 200 cases treated in this way have now been scribed [1–9] When DeCourcy [2] in 1934 reported favourable effect of partial bilateral adrenalectomy 8 patients with severe hypertension he stated his lief that elevation of the blood pressure was due excessive secretion of adrenaline by the adrenal dulla There is now good evidence that except phaeochromocytoma hypertension is not associated h increased secretion of adrenaline or noradrena e and it is the adrenal cortex that plays the more portant part in pathogenesis Whether its rôle is imary or secondary has been debated at length [10] support of a primary rôle is the clinical evidence at many patients with hyperadrenalism have pertension and that removal of an adrenal cortical imour or total or subtotal resection of bilaterally perplastic glands abolishes the symptoms and signs Cushing s syndrome and often restores the blood essure to normal Conversely hypotension is a ature of Addison s disease Thorn and his associates [9] ve reported that the blood pressure fell to normal in ypertensive patients in whom adrenal insufficiency veloped and in 1 of them hypertension recurred en deoxycortone was given But there is still evidence that essential or renal hypertension is ociated with increased adrenocortical activity with the formation of abnormal adrenocortical rmones and the majority opinion is that adreno-tical hormones have a secondary action which ows other factors to elevate the blood pressure LDBLATT [11] first observed that hypertension induced perimentally by constriction of one renal artery could abolished by adrenalectomy Other workers [12 13] ve shown that in rats adrenalectomy abolishes the pertension which follows nephrectomy in single imals or in animals linked in parabiosis There is no evidence that the adrenal glands maintain this iprival hypertension through their action on ter and salt metabolism [14] because at least in single imals ingested sodium chloride is a partial substitute the adrenocortical hormones

Adrenalectomy is much safer now that it can be lowed by adequate substitution therapy with cortisone (though in some cases deoxycortone is also required) The results are difficult to assess for several reasons Observations on the effects of rest alone [15] of hypotensive drugs,[16] and of sympathectomy [17] have shown that spontaneous variations in the blood pressure may be profound, and that any operation may cause a fall in blood pressure Hence it is difficult to obtain satisfactory controls Furthermore the results of adrenalectomy have been assessed by different criteria—in some instances by the effect on the blood pressure alone in others by the effect on symptoms and signs Nor has the operation been uniform In most cases the patient has undergone subtotal bilateral adrenal resection , and some but not all, of these patients have required postoperative substitution therapy Only a few have undergone total adrenalectomy [9] Understandably there has often been 'surgical polypharmacy —adrenalectomy combined with removal of a diseased kidney or with bilateral sympathectomy In the largest published series [5] Adson type sympathectomy has been combined with total or subtotal adrenalectomy Finally some of the patients have had essential hypertension and others unilateral or bilateral renal disease Since the operation is experimental it has been undertaken mainly where the hypertension has been severe (diastolic pressure greater than 120 mm Hg), the patient has failed to respond to intensive medical treatment and there has been evidence of progressive damage to the heart kidneys brain or—particularly—the eyes Because of the high mortality from operation and short postoperative survival in patients with nitrogen retention any impairment of renal function is now accepted as an absolute contra indication to adrenalectomy

Of the 125 patients operated on by the Philadelphia group [5] about a third had a reduction in blood pressure to 150/100 mm Hg and in a further quarter or so the diastolic pressure after operation did not exceed 110 mm Hg Bowers [1] claims that, in a series of 27 patients operated on all but 1 of the 21 survivors subsequently became normotensive DeCourcy [3] claims similarly good results , but in view of the spontaneous fluctuations in blood pressure it is difficult to assess the result when only isolated readings are given The Boston group,[9] who did total adrenalectomy alone give more detailed blood pressure readings Of 12 patients operated on 9 survived three months or longer , and of these only 2 showed a definite fall in blood pressure Despite a profound fall in pressure some patients have died soon after operation of coronary thrombosis or cerebrovascular accidents On the other hand some patients have been relieved of their symptoms and the eye ground changes have regressed without any significant change in blood pressure—a response that has also been observed after sympathectomy alone One of the most striking changes after adrenalectomy is increased loss of urinary sodium and chloride and in several patients this has led to the disappearance of congestive cardiac failure or pulmonary oedema Although a significant fall in blood pressure late in

convalescence has always been preceded by increased excretion of sodium, loss of this electrolyte is not always accompanied by a decrease in basal blood-pressure ROSENHEIM [8] has reported a case in which there was severe postoperative hypertension despite biochemical findings which indicated advanced adrenal insufficiency Thus the rôle of the adrenocortical hormones and electrolytes in maintaining hypertension remains uncertain In the words of JEFFERS et al [5]

> " This is an experimental approach which cannot at present be recommended as a treatment for hypertension As in the case of sympathectomy, one cannot predict which patients will respond with improvement nor can we discern why certain patients with adequate renal function have failed to improve after operation "

## Peripheral-nerve Injuries

EARLY in the 1939–45 war the Medical Research Council appointed a Nerve Injuries Committee under the chairmanship of the late GEORGE RIDDOCH, and this formed a focal point for the five centres for nerve injuries which were set up as part of the Emergency Medical Service The collaboration of the Services and the Ministry of Pensions ensured that large numbers of patients with serious nerve injuries reached these centres and attended for review for several years after operation Although the staffs at the five centres naturally approached the problem of peripheral-nerve injuries differently, certain standards of thoroughness, methods of examination, and criteria of recovery were followed at each centre, so that experience gained at one could be measured against that at another, to the advantage of both This vein of uniformity has enabled the Nerve Injuries Committee of the M R C to present the combined experience of all centres in a special report [18]

Some fundamental experimental work on the processes of nerve degeneration and repair was being done at Oxford by a team under the stimulating guidance of J Z YOUNG These early studies showed that after a crush injury in which there was degeneration of the axon and myelin sheath the axon tips regenerated at the rate of about 4 mm a day They also showed that, besides the time taken in the axon tips travelling along the " Schwann tubes," there was an initial delay at the site of injury and some delay between the tip of the axon reaching the end-organ and the return of function In laboratory animals this stage of functional recovery was reached at a rate of 2–3 mm a day, and H J SEDDON, P B MEDAWAR, and H SMITH (1943) found that in man likewise the radial nerve regenerated steadily, though at the rather slower rate of 1 5 mm a day RUTH BOWDEN, summarising later work, now shows that the rate of recovery gradually falls off in covering the fairly long distances for nerve regeneration in man, and she points out that the closer the lesion to the spinal cord the faster is the rate of advance But with a high lesion, though the initial progress is faster than with a low one, the outlook is not on that account better

Peripheral nerve injuries give rise to difficult problems in diagnosis and in treatment An excellent illustrated pamphlet, prepared by SIR JAMES LEARMONTH,[19] was widely used during the war and w doubt responsible for many patients being sent nerve injuries centre for fuller investigation. exhaustive clinical examination was supplem by sweating and electrical diagnostic tests, a Edinburgh by a detailed study of the vascular c in nerve injury (described by R L RICHARDS report) The many early difficulties experienc A E RITCHIE and P BAUWENS in electrical dia of nerve injury led to the construction of a apparatus to deliver a " square " wave, the inte and duration of the stimulus being variable Fu rightly suggests that the widely used galvan faradic stimulators for electrical diagnosis shou replaced by a simple stimulator delivering different lengths of shock, of about 1 and 300 m Denervated muscle would require a substantial inc in intensity in changing from the long to the shock, but a normal muscle would not

R B ZACHARY and R ROAF have anal 1500 case-records of lesions in continuity, and lated the clinical and pathological findings in a siderable proportion of these The steps in the dia of a lesion in continuity are (1) distinction bet a degenerative and a non degenerative lesion, (2) subdivision into cases of complete and of inco paralysis, bearing in mind that anomalous inn is common Of 739 cases of complete paralys to open injuries, 621 had complete or partial d of the nerve—a strong indication for explor operation with a view to repair Among c injuries causing complete paralysis, division (c or partial) was very much less common (11 out of Even incomplete paralysis due to partial div is sometimes amenable to repair, and ZACHARY ROAF define those syndromes which are with partial division of the nerve Repair of injuries by direct suture remains the surgeon's contribution Criteria of recovery at all five were similar, and well over 1000 cases of suture which had been followed up for at least years have been analysed by ZACHARY Resul best after suture of the radial nerve; worth improvement ensues in about two-thirds of the Suture of the median nerve is followed by retu sensibility to the tips of the fingers in half the and even with the ulnar nerve some function ret to the interossei in nearly the same prop Improvement after repair of the sciatic nerve often been regarded as so slight that amputation been advised when this nerve is divided Yet th muscle can become strong in at least half the and although there is little sensory recovery m the patients can feel a strong painful stimulus foot Moreover, even with no sensory recovery the foot is by no means useless, provided the and joints are well cared for

One of the most remarkable features of the su of peripheral nerves in the late war was the esta ment of nerve grafting as a reliable measure direct suture was impossible or unlikely to pro a satisfactory result Experimental studies on gr are summarised by F K SANDERS, and SE describes his considerable experience with this

neral Nerve Injuries Edited by H J SEDDON *Spec Ser med Res Coun Lond* no 282 H M Stationery 1951 Pp 451 55s

[19] Aids to the Investigation of Peripheral Nerve Injuries. War Memorandum No 7 H M Stationery Office 194

ie at Oxford The criterion of success in grafting covery as good as that by direct repair of a small in the same nerve at the same site The most ing successes have been with the median nerve its, using either several strands of a cutaneous ve or a portion of a main trunk—e g , the proximal np of an irreparable ulnar nerve Successful results almost half the cases of nerve grafting is a con rable achievement, and SEDDON's account of this k is a fitting conclusion to this comprehensive ew of British experience in the treatment of pheral nerve injuries in war time

## Raynaud's Phenomenon in Industry

UNDER the Industrial Injuries Act benefit is pro ded for injuries caused by accident arising out of in the course of employment and for certain ases due to the nature of employment Such dis es are prescribed in regulations and are accordingly wn as ' prescribed diseases ' In 1946 the Court Appeal awarded compensation to a workman who med to have developed Raynaud s phenomenon ough the use of a high frequency vibratory tool In ther cases, heard in the Court of Appeal and the use of Lords, the 1946 decision was not wholly tained and in 1949 a tribunal consisting of the lustrial Injuries Commissioner and two deputy com ssioners decided that the incapacity due to Ray ud s phenomenon was not allowable under the lustrial Injuries Act At this stage the Minister of isions and National Insurance asked the Industrial uries Advisory Council to consider whether Ray d s phenomenon should be brought within the by being added to the list of prescribed diseases— s already treated as a prescribed disease in several er countries The inquiry, undertaken by the ustrial diseases subcommittee in the words of the jority report[1] " has been a difficult and protracted "

any investigation into Raynaud s phenomenon ing from long continued use of a vibratory tool is atly handicapped by the lack of data concerning ncidence in various industrial procedures Workers already have dead fingers may be loth to ig it to the doctor s attention, for fear of transfer less well paid job , and from the other side the nagerial staff do not actively invite complaints phenomenon has been described in association h many procedures involving vibratory tools— l-driven polishing, pneumatic drilling shoe pound light riveting hammers, and hand grinding ATE and DRUETT[2] using a piezo-crystal recording nique suggested that the critical frequency range 40–125 cycles per second Many other variables be of equal or greater importance including, for ance amplitude and wave-form of fundamental secondary harmonics strength of grip used, e of material on which the work is done the rator s skill the mechanical efficiency and mass of tool and the operator s susceptibility to the dition Susceptibility varies greatly whereas one ker will complain of Raynaud s phenomenon nin months another under identical conditions may never be troubled A further difficulty is in diagnosis Raynaud's phenomenon due to vibratory tools is unassociated with objective signs other than the colour changes in an attack, and often these are not easily precipitated under laboratory conditions Even if the presence of Raynaud's phenomenon is confirmed how can its association with an industrial process be evaluated ? It has long been recognised that white fingers may develop in a wide range of vascular and systemic diseases, and correct diagnosis may depend not only on detailed clinical and laboratory investigation but also on patient follow up Nevertheless clinicians agree that in the vast majority of cases Raynaud s phenomenon due to a vibratory tool can be diagnosed with reasonable confidence, though the severity of the lesion and the incapacity are more difficult to assess The conclusion of the majority report is that Raynaud s phenomenon rarely interferes greatly with the patient s work But it may affect his leisure hours for gardening, swimming, and other outdoor activities may be impossible for him, and, once established symptoms do not appreciably abate even though the patient abstains from the employment which has given rise to the disorder Having considered all these factors the majority of the subcommittee concluded that any form of prescription of Raynaud s phenomenon would give rise to serious and probably insurmountable practical difficulties especially in deciding individual claims and they advise therefore against its prescription In contrast the minority report which recommends that Raynaud s phenomenon should be a prescribed disease points out that everyone agrees that this condition occurs in industry, and this being so it is the Minister s responsibility to see that competent doctors are made available for diagnosis, as with other prescribed diseases

The situation therefore is still unhappy Possibly a more satisfactory outcome would follow further investigation into the incidence of Raynaud s phenomenon with various industrial procedures involving vibratory tools and the substitution where possible of innocent techniques for those incriminated Such a solution may not be universally feasible, but it could certainly eliminate most of the more harmful occupations

## Heroic Days

> In the natural sciences these are and have been and are most surely likely to continue to be heroic days. Discovery follows discovery, each both raising and answering questions, each ending a long search and each providing the new instrument for new search

NO ONE, perhaps, has a better right to speak of the wonder and terror of our times than J ROBERT OPPENHEIMER, director of the Institute for Advanced Study at Princeton University, formerly a most distinguished adviser of the American government on atomic policy, and now (since the investigation of his character and associations by the Atomic Energy Commission last June) denied all further access to that policy He was speaking, at the celebrations of the 200th anniversary of the founding of Columbia University on the theme chosen for that occasion ' Man s right to knowledge and the free use thereof ALISTAIR COOK in quoting parts of his address in the *Manchester Guardian* of Dec 29, says that OPPENHEIMER narrowed it for his own purposes to "the prospect in the arts and sciences", and within this framework demonstrated a world upheaved A distant survey of the human scene shows what passes for progress

[2] gate J N Druett H A *Brit J industr Med* 1947 4 141

> "that more people are engaged in scientific research than ever before that the Soviet world and the free world are running neck and neck in the training of scientists that the social sciences are pursued actively in America, Scandinavia and England, that there are more people who hear the great music of the past, and more music is composed and more paintings are painted"

But, with more means of communication than ever before, we can speak to each other less The artist, who depends on a common sensibility and culture, on a common meaning of symbols, on a community of experience and common ways of describing and interpreting it, finds himself speaking to air "His audience must be man it must be man, and not a specialised set of experts among his fellows", but the familiar concept of man is dislimning and his common cultural inheritance is shredding away For, though the songs and stories of one half of the world are being sung and told in the other half, the highways—"the super highways"—which carry them leap over the village footpaths and the small roads that join one small community with another They are the means by which we are reminded of famine or war in remote places, but "they are also the means by which the true human community, the man knowing man, the neighbour understanding neighbour, the schoolboy learning a poem, the women dancing, the individual curiosity, the individual beauty, are being blown dry and useless The means by which the passivity of the disengaged spectator presents to the man of art and science the bleak face of inhumanity"

Like the artist, the scientist is separated from his fellows—"by long years of study, specialised vocabularies, arts, techniques, and knowledge, from the common heritage even of a most civilised society, and anyone working at the frontier of such science is in that sense a very long way from home" He is far, too, from the practical crafts in which his techniques, like the artist's, have their origins

In our somersaulting world we are stunned by the new things showering round us, all potentially good, some potentially dangerous beyond all former imagining

> "What is new," OPPENHEIMER said, "is that in one generation our knowledge of the natural world engulfs, upsets, and complements all knowledge of the natural world before The techniques, among which and by which we live, multiply and ramify, so that the whole world is bound together by communication, blocked here and there by the immense synopses of political tyranny The global quality of the world is new our knowledge and sympathy with remote and diverse peoples, our involvement with them in practical terms, and our commitment to them in terms of brotherhood What is new in the world is the massive character of its dissolution and corruption of authority, in belief, in ritual, and in temporal order Yet this is the world we have come to live in The very difficulties which it presents derive from growth in understanding, in skill, in power To assail the changes that have unmoored us from the past is futile and in a deep sense I think it is wicked We need to recognise the change and learn what resources we have"

What resources have we? He had an answer, an old sound one

> "We shall have a rugged time of it to keep our open and keep them deep, to keep our sense of b and our ability to make it, and our occasional ab see it, in places remote and strange and unfamili shall have a rugged time of it, all of us, in keeping gardens in our villages, in keeping open the m intricate, casual paths, to keep these flourishin great open windy world, but this is as I see t *condition of man, and in this condition* we ca because we can love one another"

This is, and always has been, practical adv hard to follow, and it does not come newly eve OPPENHEIMER, for he gave it last year, in hi Reith lecture,[1] perhaps with a less heavy heart.

> "As for ourselves in these times of change," h *then, "of ever increasing knowledge, of collective* p and individual impotence, of heroism and of drud- progress and of tragedy, we too are brothers"

He spoke too of the noble and spacious [illegible] science

> "We go in and out, even the most assiduous o not bound to this vast structure One thing w throughout the house there are no locks, there a shut doors, wherever we go there are the signs usually the words of welcome It is an open house, to all comers"

Is it still open? And how should it be kept He himself paid tribute to the universities, as munities in which artists, musicians, poets, scientists gather in fruitful companionship and e in the great task of teaching Here, if anywhere, doors in the house of science are unlocked [illegible] not unlocked everywhere, however, and it is wel we should keep this in mind, for there is a poi which the passivity of the disengaged spectator ca be distinguished from the passivity of the dazed by advancing headlights BERTRAND Ru in an unforgettable broadcast, has shown ou plainly—not as members of this or that c supporters of this or that form of government, as humankind

One question in particular needs a quick careful answer if science discovers secrets potentially dangerous that they cannot safely confided to humanity at large, to whom can they be confided? To politicians? To select comm selected on other grounds, probably, than their occupation with the good, the true, and the beauti Today we cannot act upon, and can barely d "man's right to knowledge and the free use there a concept perhaps worth dying for The doctrine—"man's right to secrets and the excl use thereof'—has triumphed in our heroic d and is fast creating a world fit for heroes, but heroes, to live in Does the nobler concept greater risks?

## Coloured Food

AT present, with a few specified exceptions any c ing matter may be added to food. The Food Stan Committee has now recommended[3] that the Public H (Preservatives, &c, in Food) Regulations, 1925–53, be amended so as to permit the use in foods of spe colours only Representations on the committee's re mendations may be submitted up till March 31 t joint secretary of the Preservatives Subcomm Ministry of Food Great Westminster House, Hor Road London, S W 1

# Annotations

## OUTLOOK FOR THE AMPUTEE

1950 the Ministry of Pensions set up a medical mittee with Sir Ernest Rock Carling as chairman to ider whether amputation of a limb, and subsequent ing of a prosthesis, can initiate or aggravate cardio ular disorder and whether such amputation reduces expectation of life These questions proved unex edly hard to answer An interim report published 951 was somewhat inconclusive and the majority rt[1] in 1953 brought in a new factor by suggesting men who have suffered major sepsis—with or with amputation—have a higher late incidence of cardio ular disease and an earlier average age of death he hope of putting its findings on a firmer foundation committee then arranged with the Ministry for the ical examination of some 5500 pensioners, of whom ) were to be amputees and 1000 were to be controls ortunately so many of this sample failed to attend no firm conclusions could be drawn

evertheless having reviewed the whole of the lence at its disposal the committee has now been able each some ultimate conclusions ' which seem fairly r On the question of expectation of life it says t starting for example with 100 amputees alive in 0 25 had died by 1950 compared with 23 of the eral population of comparable age and sex Of 100 unded pensioners alive in 1930 26 had died by 1950 npared with 24 of the corresponding general popu ion Both for the amputees and for the wounded sioners, the mean annual mortality rate was just r 1 per 1000 in excess of that of other people On the committee comments

> With so small a difference of total mortality the actual ribution among the certified causes of death assumes very e importance Some members of the committee think within the limitations of the statistical material available e is evidence of some slight excess of cardiovascular disease ompared with the normal population with a consequential iency of deaths from other causes. The committee as a le however are still of the opinion indicated in the rim Report that cardiovascular diseases have not been erienced more frequently to an extent of any significance ngst the causes of death in limb amputees as compared those with serious leg wounds without amputation
>
> Some amputees, especially those with a high thigh outation, necessitating a tilting table with excessive ity or with severe stump pain find the wearing of a thesis an increasing burden as age advances. These may rve individual reconsideration though other classes of sioner will also find their disabilities more burdensome the passage of time Neither as regards their mortality their morbidity do amputees form a class apart They e neither a higher mortality rate nor a higher cardio ular rate than other classes of seriously wounded

ving reconsidered the evidence on sepsis as a factor committee feels that the importance of this was over phasised in its last report It concludes with the owing answers to the questions put to it

> Limb amputations, and the subsequent wearing of a thesis do not in time produce effects on the body as a k which may initiate or aggravate cardiovascular rders to any significant extent There is no material rence between the mortality rates of amputees by reason amputation and that of the corresponding rates for sioners who have suffered wounds not leading to ampu ion Such excess as there is in both classes over that in the eral population is quite small. [2]

## APICAL LOCALISATION OF PULMONARY TUBERCULOSIS

As we recently noted[1] experimental evidence supports the hypothesis that the apical localisation of pulmonary tuberculosis is the outcome of relative anæmia due to the erect posture Dock[2] noted that the pulmonary arterial pressure was too low in comparison with the force of gravity to maintain flow in the upper third of the lungs of adults who were sitting or standing Thus few antibodies and macrophages were brought to the apex toxins were no longer diluted and removed and the resulting changes in gas tension by which $O_2$ tension is raised and $CO_2$ tension reduced were believed to favour growth of the tubercle bacilli in this region Dock[3] has now reviewed more recent work, which confirms the earlier findings with regard to the inadequate pulmonary arterial pressure in the erect posture, the changes in gas tension in the apical and lateral parts of the lungs with changes in posture and some of the effects of growing tubercle bacilli in altered concentrations of $O_2$ and $CO_2$ as found in systemic and pulmonic arterial bloods He also cites the observations of Scott et al[4] These workers anastomosed in monkeys a pulmonary or a lobar artery to a systemic artery or ligated a pulmonary artery or one of its branches (thereby also making the blood-supply systemic via the bronchial arteries) and showed that the lung or part of lung receiving systemic blood developed tuberculous processes more severely than the rest of the lung receiving pulmonic blood whether the tubercle bacilli were injected preoperatively (to give equal seeding all over) or postoperatively (thus giving heavier or earlier seeding to the pulmonic supply) whether inoculated with larger or smaller doses of bacilli or whether inoculated intravenously or subcutaneously in other words the higher $O_2$ tension in the systemic arterial blood was the chief factor in causing larger lesions, and changes in lymph flow were unimportant Dock states: Scott's experiments force one to accept the conclusion that only levels of gas tension are involved in protecting the base or in favouring tuberculosis at the apex This statement seems to take Scott's experiments rather out of their context Scott and his co-workers were giving the monkeys a primary infection with tuberculosis Dock is applying their results to explain the site of reinfection ' tuberculosis (autogenous or exogenous)—surely a very different and much more complicated problem

The present view[5] is that resistance of the body to invasion by tubercle bacilli resides in the mononuclear cells that accumulate around the bacilli assisted by unknown humoral factors Florey also points out[6] the difference between the reaction in an animal not previously infected and one previously infected or vaccinated and the earliest changes in animals are essentially the same as those in man In a previously uninfected animal during the first few days after inhalation of a few bacilli the organisms are taken up by mononuclear cells in the alveolar walls and multiply rapidly intracellularly without any surrounding cell reaction after eight days the cell reaction begins and this proceeds to necrosis During these first six to eight days the bacilli are known to spread along the lymphatics In a previously infected animal on the other hand a very active cell reaction starts in the first few days and the bacilli apparently remain unchanged in the mononuclear cells they are fixed to the site and do not spread along the lymphatics early In the human lung primary infection

may occur at any site, if the infecting dose overcomes the natural resistance In people with acquired resistance, the factors responsible for this resistance cannot, owing to the erect posture, be brought so easily and in sufficient quantity to the upper thirds of the lungs (especially on the right side, because of the obtuse angle and longer branches of the right pulmonary artery), and because of the differences in gaseous tension bacilli grow most rapidly in the apical regions, and thus most lesions occur at the apex That the circulatory factor does not affect only the gaseous tension is also suggested by the collection of siliceous dust, and the resultant scars, at the apices,[7] where the particles in the macrophages stagnate though elsewhere they are removed by the bronchi and lymphatic channels This difference cannot be due to differences in gaseous tension

It seems unreasonable at present to regard one factor as solely responsible for the localisation of tuberculous lesions in the upper third of the lungs While Scott's experiments show the undoubted importance of differences in gas tensions in influencing the growth of tubercle bacilli, the factors involved in the host's resistance cannot be ignored Scott's experiments give no support to Smith's "stream flow" hypothesis[1 8]

## SUSCEPTIBILITY OF MENINGOCOCCI

THE change in the susceptibility of many strains of pathogenic staphylococci to penicillin (and in some cases to the antibiotics administered by mouth), and the emergence in the late war of sulphonamide-resistant hæmolytic streptococci and gonococci, point to the need for periodic re evaluation of the chemotherapy of infections Surprisingly, in meningococcal meningitis sulphadiazine has remained the drug of choice for upwards of fifteen years During the war time epidemics in the U S A the sensitivity of meningococci to sulphadiazine decreased very little,[9] and this decrease has never been shown to have materially affected the clinical response to the drug

Love and Finland[10] have tested the *in-vitro* sensitivity of 50 recently isolated strains of meningococci to eleven antibiotics and to sulphadiazine Weight for weight, penicillin was by far the most active agent and erythromycin ranked next, while polymyxin B and bacitracin were the least active Sulphadiazine, chloramphenicol, aureomycin, oxytetracycline, tetracycline, streptomycin, neomycin, and carbomycin had intermediate activity The strains varied within a narrow range in their sensitivity to each of the antibiotics, but their susceptibility to sulphadiazine varied over a wide range Of the 50 strains, 6 were moderately resistant to sulphadiazine according to the in vitro test used, but the remainder were completely inhibited by 50 µg per ml (5 mg per 100 ml) or less—which is well below the highest level of sulphonamide that can readily be maintained in the blood and cerebrospinal fluid of patients Even the 6 rather more refractory strains might have been inhibited by the dosage of sulphonamide used in Great Britain for severe infections[11] Comparison with the sensitivities of strains isolated and tested in or before 1945 gave no evidence of increasing resistance of meningococci to penicillin

It would seem from these results that sulphadiazine should still be the drug of choice in meningococcal meningitis, but that in the exceptional case where the clinical response seems to be delayed sulphadiazine might usefully be supplemented by chloramphenicol orally (since it penetrates well into the cerebrospinal fluid) or by penicillin intramuscularly and intrathecally

## ELECTROLYTE DEPLETION IN PYLORIC STE

JUST as the hope of a universal *therapia magna* *sans*, aroused by the discovery of antibiotics, has dimmed by the emergence of bacterial resistance and sensitivity reactions, so the quest for "a few r rules" in treating electrolyte disorders seems d to failure because of the complexity of the di ances Commonly further disturbance is cre treatment directed at a single biochemical abnor The use of ammonium chloride to reduce a raised reserve[1] may be a case in point, for such treatment aggravate any concurrent depletion of base, and intoxication has in fact been observed in infant pyloric stenosis treated in this way[2] There may fallacies in arguing from the composition of the flu from the body to the likely electrolyte disorder, homœostatic mechanisms for one ion may be efficient than for another, so that the final res not be a simple subtraction of the fluid lost fr "normal" body fluid, but will be modified by in renal excretion of ions, and possibly by trans ions between cells and extracellular fluid

Black and Jepson,[3] in balance studies on p stenosis in adults, have defined the varied patter electrolyte depletion that may be found in patients, and they suggest that the raised alkali commonly found in patients with this condition be simply explained in terms of alkalosis conse loss of chloride in the vomited material During rec five patients with pyloric stenosis retained amount sodium, chloride, and potassium considerably than the amounts retained by patients who had un gone partial gastrectomy for peptic ulcer uncompl by stenosis The retention of base (sodium + pota was greater than that of chloride, suggesting that original depletion had been of base even more tha chloride The patients varied considerably in proportion of sodium to potassium in the retained some having been dehydrated and others retaining potassium than sodium In seeking to account disappearance of "alkalosis" observed on a régime actually provided more base than chloride, Black Jepson postulate that the alkalosis demonstrat extracellular fluid was matched by an even gr intracellular-fluid acidosis Evidence of this fea association with potassium depletion has been experimentally both in animals[4] and in man[5] F studies by Darrow's group[6] demonstrate that rats a high intake of bicarbonate will have an increased bicarbonate level only when their potassium inta severely restricted, and that the "alkalosis" induced can be corrected by potassium bicarbonate

These observations tend to emphasise deplet potassium rather than of chloride as the cause of e cellular alkalosis in patients with pyloric ste Potassium depletion has also been demonstrated in p stenosis by the finding of low serum levels,[7] by biopsy,[8] and by an observed increase in exchan potassium during recovery[9] Black and Jepson that administration of saline, which accentuates sium loss, should be reserved for patients wh clinically dehydrated Potassium salts should be by mouth, and there is some evidence that these absorbed even before the obstruction has been r by operation These workers condemn amm ide in view of the absence of any chloride deficit not ered ' by an equal or greater deficit of base In ion to the risk of water intoxication ammonium ide given in these circumstances might be expected nd to further loss of base from the body and to ivate the intracellular acidosis

## VISCERAL EPILEPSY

CENT work on the electrical activity of the brain strengthened the clinical impression of over fifty ' standing that paroxysmal visceral disturbance sometimes be epileptic The syndrome is of interest everal reasons. First it is a problem in differential osis and if it is not recognised needless alarm and dominal operations may ensue Secondly the clinical ure is contributing to our knowledge of visceral esentation in the cortex the association of visceral psy with a local cerebral lesion or a focus of abnormal rtical discharge has shown that the medial aspect he temporal lobe is involved in visceral activity and ation Finally such cases display the linkage between psy and migraine for the paroxysmal visceral urbance of cyclical vomiting which is widely gnised as a prelude to migraine in adult life, is occasionally associated also with later epileptic cks, with or without migraine. Dr Wallis elsewhere his issue describes some cases of the condition His riptive term ' masked epilepsy ' is perhaps unfor ite since it harks back to a time when both the ical and the electro-encephalographic pictures of eral epilepsy were less well defined Nevertheless cases illustrate well the clinical setting and the gnostic pitfalls Usually the disorder first shows itself childhood and anticonvulsant drugs are valuable in diagnosis and in treatment.

## DIAGNOSIS OF PERICARDIAL EFFUSION

sterman and Thomas [1] have emphasised the value rapidly enlarging heart shadow on successive radio hs in the diagnosis of pericardial effusion but this is present only before all the fluid has formed, and the diagnosis may be more difficult Williams and tter [2] have reviewed a series of 17 cases all with iac tamponade and found that in 11 of these diagnosis was missed by at least one physician at the examination Symptoms were of little help for the monest—dyspnœa—suggested heart-failure or pul ary disease and cough was not a constant feature was present in half the cases, and only when this substernal and worse on respiration did it seem y to suggest the underlying condition Misconcep about the signs in cardiac tamponade were respon for the diagnosis being missed or rejected For mple often the apex beat was regarded as too easily or the heart sounds were thought to be too audible, any significant amount of fluid to be present while minent ventricular pulsations on fluoroscopy and of variation of the heart shadow with position ngly influenced other examiners A large effusion produce all the well known signs, but it does not riably do so and the classical quiet heart may be oncertingly loud and obvious. These misconceptions usually based on faulty textbook statements or nical lore handed on by teachers without verifi on but occasionally the physician was led astray his own common sense but incorrect deductions signs were often missed a rising venous pressure pul us paradoxus Increasing venous pressure missed usually because the physician expected ly distended neck veins in the upright position; iams and Soutter never found these but they did evidence of venous pulsation at the root of the neck ery patient but one They regard this as an important sign of raised venous pressure The paradoxical pulse although traditionally associated with tamponade, can occur in healthy people and be absent in those with an effusion It is best detected by careful measurement of the systolic blood pressure; a drop of 10 mm Hg or more during inspiration suggests its presence but this sign must be distinguished from the pulse alternation found sometimes in left ventricular failure

Although pericardial effusion causing tamponade is common early diagnosis is important, because treatment may be life saving and the diagnosis becomes increasingly difficult as the condition worsens with falling cardiac output and collapse Hæmopericardium should be borne in mind as a cause of tamponade; it has been described [3] as a complication of anticoagulant therapy for myocardial infarction and so may become commoner Here early diagnosis is especially important

## ENDOGENOUS VITAMIN $B_1$ DEFICIENCY

It is generally — and justifiably — accepted that Wernicke's encephalopathy is the result of aneurine (thiamine) deficiency In the great majority of cases [4] there is clinical evidence of lack of vitamin $B_1$ Experimental deficiency in the rat [5] and pigeon [6] and thiaminase induced deficiency in farm foxes [7] produce typical cerebral lesions In Japanese prisoner of war camps [8, 9] where the diet was deficient in aneurine the condition appeared like an epidemic Artificial aneurine-free diets produce appropriate symptoms in volunteers [10] and prevent recovery of alcoholics otherwise adequately treated [11] The lesions of the disease have been well described [12] and are highly distinctive Oddly enough the only aspect that is not fully agreed on is the clinical picture But so many of the cases seen under ordinary circumstances are complicated by other conditions producing cerebral symptoms of their own that this is not surprising The picture of alcoholic aneurine deficiency is particularly confusing, and the status of Korsakow's syndrome in particular needs clarification The simultaneous presence of other vitamin deficiencies also commonly complicates the picture But the careful studies of Phillips et al [11] have established that the cases in prisoners of war described by de Wardener and Lennox [8] represent the clearest-cut examples of pure cerebral aneurine deficiency yet reported

Against this more or less clear background Feigin and Wolf [13] claim to have found the lesions of Wernicke's encephalopathy in children with no vitamin deficiency These children were aged 2–4 years and presented a fairly distinctive clinical picture of a chronic disease with inadequate growth mental defect, ataxia and eye signs All appeared to have had adequate diets and at least one had been treated with large doses of aneurine All died and necropsy showed extensive lesions indistinguishable from those of classical Wernicke's encephalopathy in type and distribution (it is surprising to find the mamillary bodies unaffected in all three but they are by no means always involved) It is easy to criticise this work The number of proved cases of cerebral aneurine deficiency that have been examined at necropsy is too few for the comparison of the histological changes to be wholly reliable No biochemical studies—not even pyruvic acid levels—are recorded

But the cases are carefully presented and soberly discussed, and the authors' views deserve consideration They think it most probable that in these cases there was a congenital defect in the metabolic utilisation of aneurine—possibly a failure of phosphorylation to co carboxylase This view is slightly supported by the fact that two of their cases were sibs and the offspring of a consanguineous marriage

"Dysvitaminoses," among which this syndrome would be included, are in bad odour for instance, Flesch[14] has effectively disposed of so called local vitamin A deficiency in the skin But this should not lead us to prejudge this latest candidate

## DISLOCATION OF THE EYEBALL

EXTREME proptosis occurs when the equator of the eyeball passes in front of the plane of action of the sphincter-like orbicularis oculi muscle and the eyelids close behind the globe There are several causal factors One is trauma, and others are laxity of the eyelids and shallowness of the orbits In obesity with protruding eyes the trauma may be quite trivial, as in a case, recently reported, where separation of the eyelids to instil drops caused the dislocation[15] Negroes tend to have shallow orbits and so are prone to this mishap, and Lyle and McGavic[16] have recorded the case of a Negro with additional oblique muscles which, acting as protractors, allowed voluntary dislocation of the eyes Similarly, babies have shallow orbits and the eye may be luxated by injury at birth, or in a fit of crying, when the cause may be congestion of the orbital veins, especially if the baby has been held head downwards to terminate a choking fit

Dislocation of the eyeball usually causes blepharospasm, and the patient complains of nausea and a dull aching pain in the eye Replacement is effected by gentle and constant traction on the eyelashes with firm counter-pressure on the globe , it may be necessary to use a surface anæsthetic and to inject the facial nerve Rarely, lateral canthotomy may be needed Where the optic nerve and the extra ocular muscles have not been injured the patient is usually none the worse for his experience

## PELVIC CONGESTION

FOR some years H C Taylor, of Columbia University, has been applying to gynæcology the concepts of psychosomatic medicine He now describes[17] 100 cases which fall into the "more or less well defined clinical entity" which he calls pelvic congestion The entity is well defined mainly by reason of the multiplicity of the symptoms 20 complaints are listed, of which 11 are chief complaints The table begins with low abdominal pain, low-back pain, and secondary dysmenorrhœa , and the only constant physical sign is tenderness on pelvic examination But, while most gynæcologists will readily accept the existence of the group of patients whom Taylor describes, and may term them "functional," many may find difficulty in recognising the findings which he says are typical at laparotomy "the uterus is softened, slightly enlarged and purplish or mottled in appearance The cul de sac contains an increased amount of amber coloured fluid and there is recognisable œdema of the subserosal connective tissue and sometimes of the ovary" Surely many would regard such findings as normal Of his 100 cases, only 17 had a laparotomy during the investigation (though 47 had had a laparotomy elsewhere—as might be expected in such a group) Therefore in less than half his cases was endometriosis excluded Throughout Taylor's writings there is almost no reference to this condition, which would be strongly suspected by many clinicians o symptoms and signs he describes In his latest p the word endometriosis does not appear at all , an omission is especially strange since Meigs,[18] Scott Te Linde,[19] and many others have emphasised endometriosis is very common and seemingly o increase

Taylor outlines a tentative programme of th which includes "reassurance," the treatment of version and cervical erosions when present, advoc childbirth (which temporarily alleviates symptom finally surgery in which a choice has to be made resection of cystic ovaries and hysterectomy operation is undertaken a psychiatric consult arranged Theobald[20] has claimed better resul "cauterisation of the uterus plus" (following t of Young[21] who reported benefit from cauteris the cervix) He has extended the scope of the destruction by introducing a silver nitrate st the cavity of the uterus At the same time l dienœstrol 15 mg daily for six weeks and p containing "a pure active culture of the Met Bulgarian Bacillus"

If pelvic congestion and pelvic endometric clinically so very similar, it seems reasonable whether congestion, if long continued, may susceptible persons to endometriosis—the modern of women in the childbearing years

## NEW YEAR HONOURS

IN the past two or three years relatively few honours have been bestowed on members of ou fession in this country, and it is pleasant to see s notable medical names in the New Year list P Adrian's beautiful mind and public service have won him all the most coveted scientific distincti it is entirely proper that a peerage should nov him a member of a body whose primary function ception and where his experience will be value John Stopford, who becomes K B E , is likew experimental neurologist who has brought his into administration, and his contribution to the d ment of medical schools and hospitals has been less important than his work as vice chancellor chester University for the past twenty years new knights two hold chairs at Oxford P Le Gros Clark, though known most widely as an a on the primates, is an anatomist who has mai his stimulating contact with medicine, both by logical researches and through his lively school. I Macintosh's appointment in 1937 to the first chair of anæsthetics drew attention to the new imp of this specialty , and through his pupils, his w and his work in the Royal Air Force during the has had no small share in the remarkable devel of techniques in which British anæsthetists have lead At Aberdeen and since 1938 at Edinburgh Pr Davidson has combined special knowledge of blo orders with a broad outlook on medicine he is ph to the Queen in Scotland, and his knighthood co fitly with his presidency of the Royal Coll Physicians of Edinburgh We are likewise happ among the new knights the name of Mr A A. Ge of Liverpool, whose sterling work for the Royal of Obstetricians and Gynæcologists, both as pr and previously, has well deserved recognition A medical president whose knighthood we are glad is Dr Collins, president of the British Medical Asso in Australia

To all these, and to our other colleagues nan p 95, we offer warm congratulations

# Public Health

## N ALTERNATIVE TO HEALTH CENTRES

C O S Blyth Brooke
M.D Lond D P.H., Barrister at law
MEDICAL OFFICER OF HEALTH FOR FINSBURY

For a time after the National Health Service Act me into operation health centres were held to be the ost hopeful means of fusing the public health and general edical services Today enthusiasm for health centres s waned In practice it has proved difficult to find itable sites or premises and even when they have been ilt and equipped the expense of staffing and maintain g them would probably be out of proportion to their lue A large proportion of the cost would have to be rne by rates or taxes as general practioners could rdly be expected to contribute more than the saving practice expenses

If we are unlikely to have many health centres in the ar future we must look for other means of linking the miciliary preventive and curative services A possible lution to part of the problem, which might be to the lvantage of the profession and public alike would be r the public health department to offer the G P some f the facilities he might expect from a health centre—r example clerical help The scheme would undoubt dly place a small additional burden on the State and/or he local authority but this would be minute compared ith the cost of a health centre

### HELP FROM THE HEALTH DEPARTMENT

In essence the proposal means using the administrative t-up of the medical officer of health as offices for the P.s of the district

Every 3–4 G P.s would be allocated one clerk to act as rsonal assistant To ensure continuity of service—ring lunch intervals, sickness and holidays—each erk would have a deputy who might well be the clerk another group of doctors. The clerk would take down nd type letters prepare certificates for signature (when is was practicable) telephone to hospitals nursing sociations, and other agencies to arrange for and on half of patients and to inquire about them The ctors, during their surgeries or at other times might nd it convenient to telephone the health department for essages or to ask that letters be prepared for them to gn later Occasionally the clerk might visit the doctor s rgery to file his records. When it was convenient atients could call at the health department instead of e surgery for certificates and other papers.

The clerk might also make appointments for the doctor nd try to contact him or a substitute in an emergency n this way the public by ringing the health department ould be able to get hold of a doctor quickly: and the octor need no longer have his front door and telephone ontinuously attended Such arrangement might even e extended to the evening and night by using the services f a janitor

A dressing-station might also be set up near if not tually in the health department This would be staffed y a trained nurse who would do minor dressings for atients under the instructions of the family doctor nd the doctor might also attend himself He would us be relieved of time-consuming procedures in his rgery without sending the patients to hospital The atients would save time (an appointment system would e easy to arrange) they would be saved from e impersonal atmosphere of a hospital outpatient partment, and dare I say they would have their essings or at any rate their bandages, more skilfully pplied

An essential part of the scheme would be to set aside room which could be used by G P.s as a common room r dictating and signing letters This would soon ecome a centre where the M O H and his staff would have pportunity for discussion with the G P.s, encouraged perhaps by a supply of tea and coffee Notices on matters of medical or public health importance such as the local incidence of infectious diseases could be displayed, and a few current medical journals and recent textbooks supplied

### QUID PRO QUO

It might reasonably be agreed that as help was being given to the G.P s they should bear a substantial part of the cost it seems unlikely, however that many of them would consider it worth while to pay more than a nominal sum On the other hand they might well be glad to offer some services in return Each might accept the duties *of an assistant M O H to his own patients* It would be difficult at first to define the duties that the practitioner would undertake but I am sure some such plan helpful to both sides could be evolved

The G P could for instance do rather more than he does at present to keep the M O H informed of sickness trends in his practice He might supply details which did not involve breach of confidence on patients with non notifiable diseases of epidemiological importance or the subject of special study He would advise the M.O H and the social workers on his patients even when they were not attending him He could be asked to visit them to discuss the welfare of infants, control of infectious disease care of the aged and many other subjects Only in emergencies would he be asked to visit people not on his list—for example an aged person in need who was not on any doctor's list

In all these duties he would naturally work under the M O H but the services provided for his correspondence and the transmission of messages would be confidential

Possibly experimental arrangements of this kind could be organised under the present Acts by a liberal interpretation of the expression health centre If not a short amending Act would readily establish the legal basis on which a scheme could be developed

---

## London in 1953

The dangerous situation which threatens now that the public has largely forgotten about diphtheria is again illustrated by figures given in the report for 1953[1] by Dr J A Scott medical officer of health for the County of London Despite continued publicity and further efforts by L.C C clinic doctors and health visitors the number of primary immunisations again fell during 1953, and the annual total was less than two thirds of what it was in 1949 It is estimated from the London figures that by the end of 1953 the proportion of immunised children under five years had fallen to 51 5%—its lowest level since the immunisation scheme came into full operation The report puts most of the blame on the apathy of parents and goes on to say "If the continuation of the present freedom from diphtheria is to be ensured the number of immunised children under five and particularly under one must be substantially increased without delay"

Among the vital statistics for London the report records a decrease in the death rate from 12 0 per 1000 population in 1952 to 11·6 in 1953 The cancer death rate continued to increase and there were more deaths from violence than in the previous year home accidents forming a disturbingly large part of the total The infant mortality rate was 23 9 per 1000 live births compared with 23 1 in 1952 25·4 in 1951 and 25·8 in 1950 The decline in the birth rate which has been going on since 1948 continues but it is slowing down in 1953 the London rate was 15·2 per 1000 population as against 15 3 in 1952 15·6 in 1951 15·7 in 1950 16·7 in 1949 and 13 4 in 1938

In 1953 of every 100 children born in London 88 attended a maternity and child welfare centre at least once in their first year of life—the highest recorded figure First home visits of health visitors to children under one were equivalent to 90% of the total live births The number of domiciliary confinements which has been declining since 1948 fell from

---

[1] London County Council Report of the County Medical Officer of Health and School Medical Officer 1953 [illegible]

11,026 in 1952 to 10,472 in 1953 The total of midwives qualified to give analgesia has steadily increased and since 1950 all midwives employed by the council have been qualified to do so In 1946 analgesia was given in 3% of domiciliary confinements, in 1953 the proportion was 77%

One of the L C C's tasks is to keep watch on the condition of the water in the Thames, and its chemical branch makes a weekly examination at 25 points between Teddington Weir and the sludge-dumping area in the estuary—a total distance of 86 miles The pollution load that the river can stand obviously depends a great deal on the rate of flow, and it is laid down by statute that abstraction for water-supply shall not reduce the flow over Teddington Weir to below 170 million gallons per day The summer of 1953 was by no means dry, and the average daily flow for the months of July to September was 225 million gallons Nevertheless, the condition of the river became extremely poor and was bad over a considerable stretch of its course for many weeks, particularly between London Bridge and Gravesend But the report adds that new works for the additional treatment of sewage should shortly reduce the pollution load counteract the progressive deterioration of recent yea

## Northern Ireland in 1953

The Registrar-General for Northern Ireland[1] rep that in 1953 the general death-rate, the infant mort rate, and the death-rate from tuberculosis were lower than in any previous year The death rate w 10 7 per 1000 population—0 1 below the rate for 1 and 0 9 below the average for the five years 194 The cancer death rate of 1 54 per 1000 was, howe 0 07 above the five-year average, the annual numb deaths from cancer of the lung has more than dou since 1943 The death-rate from tuberculosis (0 23 p 1000 population) compares with 0 30 in 1952, and a f year average of 0 50 The infant-mortality rate of per 1000 live births was exactly half the correspon rate in 1923 The birth-rate (20 9 per 1000 populat was the same as in 1952

## HAZARDS AND HEALTH

In his report for 1953[1] the Chief Inspector of Factories (Sir George Barnett) records that the number of accidents (181,637) in premises within the purview of the Factories Acts showed the first appreciable increase since the 1939–45 war over the previous year's total (177,510), fatal accidents, however, decreased from 796 in 1952 to 744 in 1953 Several factors contributed to the rise in the total number, among them the increased number of man hours worked and the increase in the range of processes undertaken by women workers

Particularly disquieting is the increase in accidents to young people commenting on the persistently high figures in this group, the Chief Inspector states that "Allowing young persons to be injured or killed is a form of extravagance in which British industry simply cannot afford to indulge", and he quotes examples of accidents occurring "in circumstances so deplorable that one questions whether certain employers are fit to be trusted with 'this precious raw material'" "Lack of proper instruction of young persons," the report adds, "is the greatest single cause of machine accidents", and though the blame cannot always be laid at the door of the management, better discipline and closer supervision would prevent those avoidable tragedies which result from skylarking and youthful high spirits

Referring to eye injuries, the report draws attention once more to the difficulty of getting workers to use protective devices, whether provided statutorily or otherwise Much depends upon the attitude of the management if they make it clear that they treat the matter with the utmost seriousness, then the workers also will understand the importance of taking all available precautions The law, moreover, lays down that employers are obliged "not merely to provide the protection, but to exert all due diligence to see that it is used" Some factories have adopted the excellent practice of stamping job cards with appropriate reminders where the work demands special eye protection, and other firms have successfully organised intensive propaganda campaigns, but much more rigorous legislation is needed if the number of eye accidents (7738 in 1953) is to be reduced appreciably

The provision in all factories of first aid facilities has been compulsory since 1924, and though in some the legal standards have been far exceeded, in too many others the equipment consists of "small tin boxes covered with rust and dirt, containing the grimy remnants of their once statutory contents" Similarly, the standard of proficiency of first-aid attendants varies widely A factories employing more than 50 workers are requir to have a trained attendant, but the type of trainin not defined, and no stipulation is made regarding th time that may have elapsed since the course was unde taken The factory inspectors report an increas difficulty in recruiting volunteers for first-aid duti even where financial inducement is offered thi disturbing, and it is to be hoped that some way soon be found of impressing upon managements importance of this aspect of their workers' healt

The report draws attention to the difficulty of persua ing both employers and workers that a high standard cleanliness can and should be maintained even wh the trade is essentially a "dirty" one Too often c and rubbish are allowed to accumulate in anticipati of the "*great annual clean*" The larger factories are general better maintained than the smaller establi ments, and some of the cleanest are those in which th "dirtiest" trades are carried on Associated w cleanliness is the question of ventilation, and it encouraging to note that, with the rising price of fu more and more firms are installing modern systems heating which use waste products for fuel Ho in a large number of factories the heating and systems remain obsolete The report recommends th architects should give the same attention to the venti tion of factories as they now give so successfully concert halls, schools, hospitals, and other pub buildings

The Chief Inspector observes that health is not matter merely of protection against injury or diseas "if the individual feels that he is a unit, a clock numb or a cog in a machine, not even the best provisions for physical health will compensate for his sense of los recognition as a human being" Fortunately, there signs that managements are growing steadily aware of the need for promoting the mental as as the physical well being of their employees

## SENIOR REGISTRARS

### STATEMENT BY MINISTER OF HEALTH AND JOINT CONSULTANTS COMMITTEE

The Minister of Health has been reviewing the tra plan for senior registrars instituted in 1951 in the light the numbers actually employed and the factors which w affect the number of vacancies likely to occur in t higher grades in the period in which persons who enter t senior registrar grade in the next few years will completing their training

After discussion with the Joint Consultants Committ as representing the medical profession, the Minister h come to the conclusion that generally the intake of se gistrars in the various specialties is for the time being fficient to meet future needs and that the present mber employed should be maintained pending the out ome of the discussions in which he and the Joint Com ittee are engaged on the general subject of the medical affing structure of the hospital and specialist services

---

[1] Cmd 9330 H M Stationery Office Pp 257 6s 6d

Accordingly in a letter of Dec 13 the Minister has ked hospital boards to maintain their senior registrar mplement in total and in each specialty at the number which it then stood subject only to a few minor terations

When a senior registrar completes the tenure of his esent appointment whether this is in a post within the aining plan of 1951 or in a 'transitional' post the nploying board is left free to extend his appointment for additional year so that he may have more time to mpete for a higher post if they are satisfied that his *tentialities are such that he is likely, given more time* obtain one When a post becomes vacant boards are pected to appoint to it a new senior registrar in the me specialty As hitherto there is nothing to prevent existing senior registrar from obtaining another nior registrar post in the same or a different specialty d holding it for the usual term

Senior registrars whose tenure is extended under these ew arrangements will of course continue to be free to ompete for higher posts It is emphasised, however hat their retention as senior registrars will not give them ny special claim or constitute any guarantee that they vill be successful

The Joint Committee have expressed their agreement vith these arrangements

## NEW YEAR HONOURS

The list of honours published on Jan 1 contains the ames of the following members of the medical profession :

### Baron

dgar Douglas Adrian o.m., m.d. Camb f.r.c.p.
President of the Royal Society master of Trinity College Cambridge

### K B E

r John Stopford m.b.e. m.d. Manc. f.r.c.p. f.r.s.
Vice-chancellor University of Manchester

### Knights Bachelor

ilfrid Edward Le Gros Clark m.a. Oxfd d.sc. Lond f.r.c.s. f.r.s.
Dr Lee's professor of anatomy University of Oxford

rchibald John Collins d.s.o. m.c. m.b. Sydney f.r.a.c.p.
President of the British Medical Association in Australia

eybourne Stanley Patrick Davidson b.a. Camb m.d. Edin f.r.c.p.
President of the Royal College of Physicians of Edinburgh professor of medicine University of Edinburgh.

rthur Alexander Gemmell, m.c., t.d. m.a., m.d. Camb f.r.c.s.e.
President of the Royal College of Obstetricians and Gynæcologists ; gynæcological and obstetrical surgeon to the United Liverpool Hospitals.

obert Reynolds Macintosh d.m. Oxfd f.r.c.s.e., f.f.a. r.c.s.
*Nuffield professor of anæsthetics University of Oxford*

### C B (Military)

ajor General Charles William Greenway c.b.e. m.r.c.s. q.h.s.

rgeon Rear Admiral James Hamilton c.b.e., m.b. Glasg

### C B (Civil)

on Walter Symington Maclay o.b.e. m.d. Camb., f.r.c.p.
Senior medical commissioner Board of Control

### C.M G

ril Francis Fernando o.b.e. m.d. Lond m.r.c.p.
Physician General Hospital Colombo

aymond Lewthwaite o.b.e. d.m. Oxfd f.r.c.p.
Director of Colonial Medical Research.

### C V O

Joseph Graeme Humble m.r.c.s.

### C.B E (Military)

Surgeon Captain John Henry Bruell Crosbie, m.b. Dubl., r.n. retd.

Major-General Frederick Cavendish Hilton-Sergeant m.b. Lpool q.h.p.

### C B E (Civil)

Arthur Frederic Alford m.d. Brist
Senior medical officer Ministry of Education

William Edward Lodewyk Hamilton Crowther d.s.o., v.d. m.b. Melb f.r.a.c.p.
Hon consulting physician Royal Hospital, Hobart president Medical Council of Tasmania.

Maurice Walter Goldblatt m.d. ph.d. Lond
Director industrial hygiene research laboratories Imperial *Chemical Industries Ltd*

Joseph Harold Sheldon m.d. Lond f.r.c.p.
Director of medicine and senior physician, Royal Hospital, Wolverhampton

Denis John Williams, m.d. Lond. d.sc. Manc f.r.c.p.
Civilian consultant to the R.A.F in neurology and electro-encephalography physician in charge of neurology St George's Hospital

### O B E (Military)

Surgeon Commander Thomas Wilson Froggatt m.b. Sheff r.n.

Lieut Colonel John Irvine m.b. Glasg., r.a.m.c.

Lieut -Colonel Thomas McGregor McNit m.b. Glasg., m.r.c.o.g. r.a.m.c.

Wing Commander John Hope Pool, m.d. Durh r.a.a.f.r.o.

### O B E (Civil)

Basil William Armstrong m.c., m.b. Lond
Lately medical superintendent Royal Sea Bathing Hospital Margate

David Alexander Baird m.b. b.sc. Edin
Director of medical services Somaliland.

Arthur Beauchamp m.b. Birm
General practitioner Birmingham ; for services to the Ministry of Health

Eliot Cecil Curwen m.a., m.b. Camb
Hon physician Police Convalescent Seaside Home Hove.

Weliwattage Livtris Perera Dassanayake l.r.c.p.e.
Superintendent filariasis campaign Ceylon

William Marsden Ford Robertson m.d. Edin
Medical director Lebanon Hospital for Nervous and Mental Diseases, Beirut

Thassos Charidimou Gircotis m.d. Vienna
*For medical services in Cyprus.*

George Rajanayagam Handy m.b. Lond
Visiting physician, General Hospital Colombo

William Edward Hutchinson e.d. m.d. Dubl j.p.
a.d.m.s. (civil defence) Singapore

Edward Norman Jamieson f.r.c.s.e.
Surgeon Lewis Hospital Stornoway

James Hutchinson Kennedy d.m. Oxfd
Government medical officer at Ndanga Southern Rhodesia

Arthur Gentry Pitts f.r.c.s.
Medical practitioner Waimate New Zealand.

John Herbert Owen Roberts m.d. Lond j.p.
Medical superintendent North Wales Hospital for Nervous and Mental Disorders, Denbigh

Loris Rohan Sharples m.b. Edin.
For public services in British Guiana

Walter Ansley Young m.r.c.s. j.p.
For public services in the Federation of Malaya

### M B E (Military)

Major Thomas Charles Ayres t.d., r.a.m.c. t.a.

Captain Ivor Robert Bessant r.a.m.c. t.a.

Captain Alexander Joseph Zosimus Navaratne Ceylon Army Medical Corps

Squadron Leader Ernest Sidney Odbert m.b. Dubl., r.a.f.

Major Leslie Frank Richmond t.d., m.d. Durh., r.a.m.c., t.a.

### M B E (Civil)

Mona Kathleen Bailey (née Blackall), M B Sydney
Medical practitioner in the Australian Capital Territory
Frank Howard Budden, M B Lond
M O (ophthalmology), Northern Region, Nigeria
Maria Leonora Du Toit
For medical services in the Tiv division, Northern Region, Nigeria
Jane Evans
Medical missionary in Egypt

## Medicine and the Law

### Capital Punishment

Mrs Styllou Christofi, a Cypriot, was charged with the murder of her daughter in-law She spoke practically no English and her trial was conducted with the aid of an interpreter She was found guilty and sentenced to death at the Central Criminal Court on Oct 28 An appeal to the Court of Criminal Appeal failed, and the Home Secretary decided not to recommend a reprieve She was executed at Holloway Prison on Dec 15

The hanging of a woman is comparatively rare this is only the third case since the war The case is unusually important for two reasons

First, there is some doubt as to the woman's mental condition, particularly at the time of the murder Dr Thomas Christie, principal medical officer at Holloway Prison, in a report dated Oct 5, said that after observation of the prisoner since July 30, he had formed the opinion that she was insane, but was medically fit to plead and stand trial He wrote[1]

> "The clinical picture is that of a non systematised, delusional mental disorder This is a disease of the mind In my opinion, the fear that her grandchildren would not be brought up properly induced a defect of reason due to the above disease of the mind whereby, however much she may have been capable of appreciating the nature and quality of the acts she was doing, at the time of the acts the defect of reason was such that she was incapable of knowing that what she was doing was wrong "

If Dr Christie was right in that opinion, then Mrs Christofi was insane within the meaning of the McNaughten rules A copy of his report was furnished to the defence, but on the prisoner's own instructions the defence did not raise the issue of insanity As she was deemed fit to plead, counsel had no option but to accept her instructions

After the prisoner's appeal had been dismissed, the case came before the Home Secretary If it appears to the Home Secretary that there is reason to believe that a prisoner under sentence of death is insane, he must by the Criminal Lunatics Act, 1884, appoint two or more legally qualified medical practitioners to examine the prisoner and to inquire as to his insanity In view of Dr Christie's report, the Home Secretary appointed three doctors to conduct an inquiry They reported, according to the Home Secretary's explanation in the House of Commons,[2] that Mrs Christofi was not in their view insane, and they added that in their view she did not suffer from any minor mental abnormality which would justify them in making any recommendation on me grounds relevant to the question of a reprieve T Home Secretary also disclosed that Mrs Christofi w not agree to electro encephalographic examination

Secondly, this case raises again the question of Home Secretary's responsibility and his relations Parliament At the time of the Bentley case,[3] the Spe ruled that a particular case could not be raised in House prior to reprieve or execution, but that a reprieve or execution the Home Secretary was an able to the House This ruling has obvious disadva in that execution settles a case beyond recall, but t are clearly reasons for it In the Bentley case, how the then Home Secretary, Sir David Maxwell Fyfe, receive deputations of M P s

In the present case the new Home Secretary refused receive such deputations, although he agreed "a exceptional step " to see Mr D Weitzman, Q C, M P, was counsel for the defence at the trial When questi about this in the House after the execution, he sa "I am sure that, while it is of course open to Membe Parliament to submit representations to the Secretar State, the House will agree that a Home Secretary sh not be expected to receive oral representations, even fr hon Members, and to discuss the case with them, wh he is engaged in the discharge of this onerous and an duty " After the execution, the Home Secretar asked to publish all the medical evidence and the ad given to him by the trial judge The Home Secret replied that he was not prepared to make these doc available, it would, he said, be contrary to established practice and open to considerable objectio

The Home Secretary's refusal to publish the docume makes it difficult to form a judgment on this case leaves certain questions unanswered For instance, i not clear whether the Home Office doctors expre dissented from Dr Christie's opinion that Mrs Chris was insane at the time of the murder, or whether they principally concerned with her mental condition at t time of their examination When insanity is plea at the trial, *the court is concerned solely* with t prisoner's mental state at the time of the murder, but t Home Secretary in considering a reprieve may a take into account the prisoner's subsequent mental sta

Publication of the report of the Home Office doct would have been valuable in another connection I Mrs Christofi pleaded insanity, that defence might have succeeded in view of Dr Christie's report It likely that Mrs Christofi threw away her best li defence That raises the question of how far a pris as to whose sanity there is some doubt, is the best pe to decide his or her defence It is difficult to see that right can be taken away from a person deemed to plead, and for that very reason the prerogati mercy assumes an especial importance

The legal and administrative difficulties involved these cases would disappear if there were no death pen

### Death after Ambulance Journey

The death of a 72 year old man after transfer a sitting case by ambulance from Glasgow Royal Infirm to Helensburgh Victoria Infirmary was the subjec a fatal accidents inquiry in Glasgow on Dec 23[4] jury returned a formal verdict that the man had as a result of a broken rib puncturing his lung d the journey The widow gave evidence that her hus had become very ill while sitting up throughout journey A doctor from the Royal Infirmary s that he had given instructions for the man to be tr ferred as a stretcher case A pathologist who had a necropsy said that if the patient had travelled l down the movement of the rib would have been redu

## A Letter from the Hospital

t an inquest in Doncaster on Dec 20[1] the coroner urned a verdict of suicide while the balance of the ud was disturbed in the case of a 30-year-old woman o had been found gassed in the kitchen of her home coroner said that there was a history of mental ess since the birth of a baby in October The woman been admitted as a voluntary patient to Middlewood spital, Sheffield and, according to evidence at the uest, on the day of her suicide she had opened a er from the hospital addressed to her husband ing that her condition had not improved The oner wanted to know why the letter was sent to the nan's home instead of to her doctor and why it merely a typed document with blanks filled in and ed by the clerk." 'I do not think,' he declared here is any doubt it had the final effect of making lose her balance and I think there is no question atever she decided on the spur of the moment to take life in consequence

n official of Sheffield no 2 Hospital Management mittee, whose group includes Middlewood Hospital eported to have said that the medical superintendent considering whether it might be advisable to omit reference to the patient's condition from the form t to the relatives The letter mentioned at the inquest s a statutory form laid down by the Board of Control

## Habit forming Drug

The habit forming characteristics of pethidine were erred to in a recent case in which the wife of a doctor s granted a decree for the restitution of conjugal hts[2] The husband's cross petition for divorce on the und of cruelty was rejected

he parties were married in 1941 Between 1948 and late in the wife underwent a number of serious operations and health began to deteriorate After a major epileptic fit 052 she was admitted to The Retreat York and after it three months treatment was formally discharged The wing year she again entered The Retreat and while she there the husband wrote to her that in no circumstances ld she be admitted to his house again and refusing to let see their child—a letter which said Mr Justice Wallington, ated the husband's determination to bring the marriage n end

ealing with the husband's allegations of cruelty his Lord said that it was common ground that the acts alleged due to the fact that late in 1951 the wife became a drug ict after injections of a particular drug given to her after operations. It is a synthetic drug and it was not realised some time after it appeared on the market that it was a t forming drug The judge said that he was satisfied the wife had acted to some extent as the husband had ed She pressed him for injections disturbing his rest acting him when he was attending his patients during day making him less confident in his work and less fresh ind and body

ere came a time said the judge when the husband knew out pethidine The time came when he injected the drug a frequency which he knew must have a disastrous effect is wife I am not charging him with doing anything iously wrong He was in a great difficulty and he had oose between losing his sleep and the disturbance of the and giving his wife a drug which would make her quiet dealing with this case on the footing that he did not ything which he knew to be morally wrong He was kind to her because he did not like to see her suffer "

e husband his Lordship continued had never suggested he was prevented from carrying on his practice apart from wn two illnesses, although he might have been hindered describing some of the husband's evidence as exagger to the point of improbability the judge said: I cannot that the husband has proved any danger to his health or mental as the result of the wife's conduct His ges of cruelty therefore fail

# In England Now

*A Running Commentary by Peripatetic Correspondents*

GRANNIE's passion for locks and keys was a source of unending amusement in the Smith family On her bedroom door was a Yale lock two bolts, and a hook and-eye catch Her small bureau for her papers was reported to be a honeycomb of secret drawers. She kept her keys in a purse under her pillow and in the three years I visited her I never knew her to lose grasp of this purse Indeed I believe she slept with her arthritic fingers firmly locked around it It was not that she was ungenerous; her grandchildren adored her: but she had a fixture for locks and keys. Just as many ageing folk develop a fancy for acquiring things, hoping that an accumulation of life's trappings will give them a surer hold on life itself so Grannie put away, firmly closed and locked everything hoping perhaps, to conserve and extend her own contracting days

Once when her purse burst open and her keys fell in a shower over the bed I laughed and said 'Grannie, I can see every key except the Key to the Kingdom of Heaven! Gravely she pointed to her heart and said I keep *that* one locked in here

She had a great fear of hospitals and made me promise more than once that I would never send her there It was therefore with a troubled mind that I read the pathologist's report *S typhi* isolated. I told the family that I did not think we should be sentimental about her distrust of hospitals and that I meant to send her to the isolation unit as soon as possible They were, of course in agreement. So I went upstairs to her bedroom and sat on her bed and took her hand and said Grannie I am afraid I must break my word You have got a serious illness which you could pass on to the family I have arranged for your admission to hospital. She gave me a long steady look which I shall not forget.

Before the ambulance came she gave her daughter all the keys, commanded her to unlock every lock and open every drawer and box and cupboard in the room She gave precise instructions how to slide back the panels which revealed the secret departments in her bureau Most of the drawers were empty Some contained a small amount of paper money old letters tied with ribbon, her dead husband's tobacco-pouch now containing crushed lavender, a few trinkets.

By this time the ambulance had arrived and with great composure she lay on the stretcher As she was being taken out of the door her daughter rushed up to her and said I will bring up all your keys later Grannie I have the only one I need, she said

I had a Greek girl in outpatients yesterday and asked her if she was breathless She didn't understand so in despair I asked if she had dyspnoea. Ah yes she said I have dyspnoea and you speak Greek.

* * *

The DC 3 glided to a halt in front of the little airport buildings and I stepped out into the glare of the Colorado sun feeling very British and conspicuous in my dark lounge suit among the light summer attire and gaily coloured shirts around me There was something remarkably fresh and invigorating about the air and the expanse of open country around the airport after the noise exhaust laden atmosphere and urgency of Chicago My host from the hospital was waiting and after a quick lunch he suggested a short sight-seeing drive This proved to be a modest run of 180 miles over arid desert through the picturesque little town of Montrose so different from its Scottish namesake to the Black Canyon of the Gunnison The forbidding grandeur of this grim canyon the beauty of the lakes and coniferous forests at the top of the Grand Mesa and the red magnificence of the rock formations of the Colorado National Monument which we visited next day defy description

But my visit was a professional one; the local medical society dinner was planned for 7 P.M my lecture for 8.15 P.M and at 6.50 P.M we were at the hospital The secretary of the society met us looking a trifle sheepish I'm sorry he said but the cooks thought the dinner was tomorrow night The society put its heads together and decided we should go to the president's for liquid refreshment and to think things over We climbed into roughly fifteen cars and descended upon the president's wife, who responded manfully, as American wives do At 7 45 P M it was decided that we should dine at the local restaurant, which for so small a town was remarkably sumptuous Conversation flourished, except when I mentioned the National Health Service By 8 45 P M our numbers had risen to roughly fifty, we were on Christian name terms, and the society decided that perhaps I ought to be delivering my lecture We straggled back to the hospital, and were entering the lecture room when Joe realised that he had forgotten the projector Jake sprang into the breach and into his Jaguar, and was back within ten minutes carrying a small black box, which, on being opened, unexpectedly proved to contain an electric sewing-machine But in due course another box was produced, this time the right one, and Jake atoned by acting as projectionist At 9 15 P M, provided with a broomstick to use as pointer, I began my lecture Faced with a professional topic, the audience subsided into gloom, which was rapidly dispelled a few minutes later, when the screen fell over Whether my subject interested my audience, I cannot tell, but I certainly enjoyed the evening

* * *

All men wear trousers in public, and most accept the convention of having them done up In the old days the loss of a button mattered little and the defect could be quickly remedied at home at the end of the day But with the introduction of modern closing techniques the situation has become potentially dangerous

Lately, while visiting a famous foreign clinic I had occasion to leave the room between cases, whereupon the most vital of all zips literally came off in the hand All efforts to restore the situation were fruitless Return to the clinic was unthinkable, it was too long to wait, at any rate there, and the possibility of a message to the operating-theatre for a row of Michel's clips occurred to me too late Action was imperative, and for better or worse I decided on flight Simulating confidence, looking neither to right nor left and with head erect—to increase anterior tension—I reached the hospital exit without apparently attracting attention

As luck would have it at the first corner was a clothing store But inside was a woman choosing ties for her husband She was in no hurry and the assistant showed signs of waiting to leave her to make up her mind and attend to me I feigned interest in a box of socks farther down the counter When the opportunity for explanation finally came the assistant regretted that they had no facilities for repairs but suggested a tailor farther down the street This meant another public appearance but again I excited no undue attention The next hazard was the least expected The only attendant behind the counter was a woman Flight seemed ridiculous She was middle-aged, of kindly demeanour, and wore a wedding-ring I outlined the general position She explained that the tailor himself was ill but that there was another four blocks away This distant craftsman proved to be male, but a heartless scoundrel who took full advantage of my situation zips were irreparable, he declared, and he was too busy to insert a new one that day, he advised me to buy a new pair of trousers I pointed out that none of his trousers matched my coat He replied that non-matching trousers were the current fashion in America Finally he suggested a row of safety pins and scornfully declined payment Walking delicately, like Agag, I was now able to return to the clinic, but explanations caused more entertainment than sympathy

* * *

I like to go to Guidance Clinic
And be a charming little cynic
And paint the walls all scarlet red
And hit caretakers on the head,
For this reveals my true intents
And latent talents, and prevents
The insalubrious suppression
Of all my long pent-up aggression
I like to paint the Clinic red
And hit caretakers on the head,
But, mother figure, is it true
There's *nothing* that I mustn't do?

# Letters to the Editor

## SANATORIA

SIR,—The leading article in your issue of De suggests, on the basis of some American evidence, t the introduction of antibiotics has rendered ob a good deal of sanatorium treatment

No worker in the field of tuberculosis can doub value of the new antibiotics but they have been i duced against a background of better nutrition am the poorest classes, financial arrangements that p a patient to rest in a sanatorium without eco catastrophe, the raising of the standard of trea throughout the country to the level previously en only by a few areas, enormous improvements in much wider application of surgery, and a better u standing of pathology

To treat a lesion instead of a patient is always medicine in tuberculosis it is a disaster Yet, in as if some of the patients could not be safely treated drugs whilst they work, your leader suggests pro this fallacy In any case, we know the answer It been my lot to have referred to me a considerable nu of doctors suffering from this disease Owing to quaint but widely held belief that disease always a different course in the medically qualified, they in many cases been treated by antibiotics whilst tinuing their work Without exception, they deteriorated on this régime

A young man or woman may acquire tuberc because of an overwhelming infection by a close co whilst in a susceptible state or because of greatly l physical resistance, as in semi starvation condition example, in a prisoner of-war camp More comm however, the disease arises because resistance to e genous or exogenous infection has been lowered domestic or financial difficulties, by driving ambit excess of ability, or by failure to adjust to environ If an initial minimal lesion is controlled by drugs o out by a surgeon, but the resistance not raised and te not released, further lesions are likely to arise To a patient, a sanatorium régime, if sympathetically skilfully applied, will not only enable him to overcom current infection, but will induce a state of mind a philosophy that will afford a considerable meas protection for life Whilst the smell of pine needl a rarefied atmosphere do not affect the tubercle ba directly, I do firmly believe that a patient will r more permanently if he watches the serene bea forest and meadow from his bedroom window, th he passes several months of enforced idleness lo at a factory chimney

The abandonment of country sanatoria may necessity, but let us not try to make a virtue of it of them may be unfit for the middle aged it wo a wise investment to rebuild them The Norwegia emptying their sanatorium beds but only becau are eradicating the disease and not because the keeping their active cases at work

You question the wisdom of confining "non mi young people for months in surroundings wher suffer the possibly adverse effect of being surr by others with the same disease" If the adverse referred to consists of mental depression by co from despondent "chronics," then the sanatorium indeed be a badly managed one

Finally, may I stress as axiomatic that a p who is ill enough to need treatment with antib ill enough to be in bed

Liverpool LESLIE J TE

SIR,—Your editorial does not pay the credit due late chief, Sir John Robertson As medical off h for Birmingham he it was who had learnt and ht the value of George Bodington s work, and who tuted the campaign against tuberculosis including building of the sanatoria The emphasis he placed sanatoria was in mental and physical rest in pure vith good food and where the patient s home was of right standard he regarded it as the safest and place in which to treat infectious disease The ment of pulmonary tuberculosis was to include ing unpleasant but everything which brought rest fort, cheer brightness and fresh air to the patient his family and the family doctor was the best on to undertake it

s the tuberculosis service has developed I have ched the progressive departure from these ideals tuberculous patient has gradually been taken out he hands of the family doctor by the institution pecialised techniques—pneumothorax pneumoperi um phrenic nerve paralysis thoracoplasty—and t is still more important these measures have been oted as substitutes for rest (e.g if a patient could not found a bed in a sanatorium pneumothorax was iced to rest the lung) After hundreds of thousands of ents have been treated by this means we are now that they are of little use—lung resection and acoplasty are the correct treatments But not while patient has an active focus for operation at such a can spread the infection to normal lung lung ction must not be done until the lesions have healed patients now admitted to sanatoria are told that r when they have recovered they may have to have r lung removed As Dr Houghton and Dr Corrigan ted out the patient who enters a modern sana um can no longer contemplate a period of tranquillity freedom from personal anxiety Modern sana um treatment has caused people to look upon the ase with horror therefore let us get back to teaching of Sir John Robertson Give the patient the comfort and cheer and restore the family doctor to rightful place We can the more readily do this now we have efficient drugs

mingham 15 JAMES F BRAILSFORD

IR —Your leading article poses several questions of t importance The picture as you say has been oundly changed by the antibacterial drugs and it is ly for many of the old methods to be re-examined case of the tuberculous child must, however receive ial consideration

Whilst it may be reasonable as you suggest to treat am adults with small uncavitated lesions with rs while they work this method should not be sidered in the case of school-children except under the t careful safeguards These small uncavitated lesions dult type disease in adolescents demand the closest ntion They are likely to be recent and tend to gress and spread if not dealt with energetically

For should there be any questions arising in the case children about the irritations of institutional life the possibly adverse effect of being surrounded by rs with the same disease Whilst far too many ur boys and girls still become infected with tubercu only a small proportion of the cases that come to call for prolonged institutional treatment In this p should certainly be included the rare cases of lren with adult type disease These should be itted only to sanatorium schools fully equipped both leally and educationally

obably it is true to say that tuberculous children tered in small numbers and isolated groups through the country have been neglected in the past ainly this is the case today for from time to time ig people with tuberculosis are admitted to my torium who have received previous treatment in surroundings quite unsuited to their tender years and educational needs. Numerically the problem of how best to provide for these handicapped youngsters is small Probably half a dozen comprehensive centres would cover the needs of the whole country The names of two or three readily suggest themselves All that is required is a little interest and understanding of the problems involved at the appropriate administrative levels

High Wood Hospital for Children,
Brentwood Essex. F J BENTLEY

## HÆMOLYTIC TRANSFUSION REACTIONS

SIR —I do not understand why when blood transfusion is to be discussed, so many protagonists entangle them selves with arguments on blood grouping True blood grouping is an important factor in blood transfusion but it is only one factor among several such as the collection of donor blood, its storage distribution and adminis tration and I cannot admit its pre-eminence among these Blood transfusions are given to save lives and it is our duty to remember this and not to waste our energy on sterile recriminations No two patients have the same needs, no two hospitals the same patients One hospital may receive no emergency admissions and have but a limited number of elective operations in such a hospital blood grouping can be done by the most elaborate and time-consuming methods without harm to any and with benefit to all Another receives patients from a large sparsely inhabited tract of land the patients who survive the journey to hospital will readily tolerate two or three more hours delay so slow methods may again be used (though I think a flying squad using rapid methods might not be out of place) In a city a hospital may receive all the emergency work – traumatic as well as medical—from a population of 250 000 within a radius of 3 miles here patients more often survive the journey to hospital but may arrive in the receiving room grey pulseless with air hunger and barely conscious It is for these and those a little less ill that I am con cerned : and it is with such patients in mind that I decided eight years ago that I must provide a blood transfusion service which would tolerate only the minimum of delay

During these eight years although I used the more complicated methods freely I have depended chiefly on the simplest methods So far I have killed no one, though I have made a dozen blunders but I have found that every one of these dozen blunders was due to a failure of the human element—not to a failure of the simple method being used Every blunder was revealed by simple repetition of the test by someone working without anxiety or preoccupations—often by the person who made the original mistake I therefore offer no apologies for my crude methods, for crude ' they may be called though they revealed an anti-c and an anti r

Besides this ethical problem (for I claim that these rapid methods probably save half a dozen lives a year and add only infinitesimally to the danger of trans fusion) there are the various practical points which have been brought up in this correspondence Dr Taylor (Dec 18) and Dr Walther (Dec 25) believe that tube methods are so much more reliable than any others that they must be adopted I would refer them to one paper [1] which shows that in some conditions tile methods for ABO grouping may be more reliable than tube methods and I would remind them of the method of the inclined capillary tube for Rh testing [2 3] one of my colleagues has performed [4] a direct comparison with the tube method on 2500 samples without a discrepancy The data indicate that the reliability of a serolo may vary with the surroundings in which it is performed, that a method ideal for the unhurried reference laboratory may prove less satisfactory in the busy routine laboratory Dr Walther advocates the more general use of group O rhesus negative blood, but I fear that it would prove impossible to supply the quantities required, and since it can give rise to hæmolytic reactions it would prove little, if any, safer than the simplest methods of grouping and cross-matching

---

[1] Allen, F H jun Diamond, L K Mad I n J Med 19 1 244 9
[2] Chown, B., Lewi M J cl n Path 1951
[3] Discombe G Meyer H Amer J clin. P
[4] Jacob G F Personal communication

Dr R M Heggie (Dec 18) is mistaken when he suggests that representations by any pathologist can produce an improvement in laboratories or increase of staff overnight, and that inadequacy of laboratory and staff is the fault of the pathologist Too often the pathologist's appeals for staff and space are suppressed in the medical advisory committee or refused by the management committee, and even if his pleas are granted, there must be a delay of years before buildings are erected or staff trained No pathologist can appeal to the regional hospital board over the heads of his colleagues, and if he appeals over the head of the hospital management committee, he is unlikely to obtain any satisfaction It is not fair to impute all the blame to the pathologist and to exculpate the administrator who fails to provide essential facilities

The actions of Dr J F Heggie and his committee seem to have been beyond reproach, not so those of the other bodies who circulated that memorandum There is real and widespread dissatisfaction over the dissemination of these memoranda, but this dissatisfaction could easily be overcome by the Ministry or the regional boards Every hospital management committee should be instructed to arrange for the regional transfusion director to consult with the pathologists responsible for blood-transfusion in that group, and to submit agreed and detailed recommendations on the space and staffing needed to provide an adequate service, and on the *deviations from optimal techniques which would be* needed to utilise best the existing facilities Differences of opinion would of course arise, and these could most easily be settled with the aid of members of a panel of specially experienced pathologists nominated by the Association of Clinical Pathologists

I suspect that some of the warnings given in memoranda are open to question Dr Taylor praises Dr Heggie's warning about infected blood, but I understand that Dr Heggie's experience of such accidents is limited to three cases when I encountered one of these in the High Court, the evidence suggested that the death was not caused by infected blood One should realise that the whole North London Transfusion Service has had one death from infected blood in five years, during which period more than 500,000 bottles were issued The evidence on which warnings are based should be published [5] and not restricted to some coterie of initiates

I believe that blood-transfusion becomes safe when supervised by pathologists and technicians who are interested in it and who will spend time and energy on it Such persons can use almost any method with safety

I am glad that I differ so slightly from Mr Evans (Nov 27) in my approach to treatment He admits that it is only in dehydrated patients that treatment with sodium sulphate is likely to be beneficial I submit that it is difficult during the first twelve hours, to differentiate the oliguria of dehydration from that of transfusion nephrosis, and Mr Evans admits that if you make a mistake it will kill the patient since 14 patients of 15 recovered without sodium sulphate, we need more convincing evidence of its benefits For the same reason, I deprecate exchange transfusion, because most patients will recover quite quickly without it

## SERUM TESTS FOR SYPHILIS

SIR,—In your leader of Dec 4 the incidence of specific reactions in the blood transfusion service as 0 04% of sera tested This gratifyingly low surely due to the fact that donors are drawn from young adults, a group in which such reactions expected to be rare The incidence may well be in general hospital laboratories testing sera from with a diversity of clinical conditions

Antenatal sera form a group which may be with blood donors since both represent healthy viduals In recent years at the Whitechapel Laboratory the proportion of antenatal sera positive serological (S T S ) reactions has fluctuated 0 6% but not enough of these have yet been with the treponemal immobilisation (T P I ) test more than very tentative conclusions to be drawn the incidence of non-specific reactions in have carried out T P I tests on 200 antenatal sera to the Venereal Diseases Reference "problem" sera because they had given doubtful S T S reactions in other laboratories these were found to be positive with one or more four S T S used in our laboratory, and of these, 34%, were T P I -negative, suggesting that the reactions were non-specific Although these sera highly selected group, the results suggest that proportion of positive S T S reactions in pregnancy are non-specific may not be negligible, and, in view wide extent of antenatal testing, in the *aggregate* may present a problem of some magnitude It very desirable that the T P I test should be more used to investigate this type of sera, but, for possible, it will have to be established in more than the two already performing it

It should also be stressed that the strength of the reactions is no criterion of their specificity, as the T P I test Although sera giving strongly S T S reactions are usually found to contain antibody, sufficient exceptions occur to make reliance on the S T S titre unwise

Venereal Diseases Reference Laboratory
Eastern Hospital, London E 9

A E WILK

## CORNEAL GRAFTING ACT

SIR,—The increasing numbers of inquiries received from doctors, solicitors, and the general indicate that the provisions of the Corneal Grafting (1952) need further elucidation, especially with to the bequest of donor eyes Briefly, the Act person to make a verbal or written bequest of his eyes for therapeutic purposes but the bequest nullified by the objection of surviving spouse or relative

The collection of donor eyes is the responsibil those who require them, subject to the provisions Act, and collection entails a certain amount of tion and effort in practice, death is usually the hospital by the doctor in attendance or by The duty team then proceeds to collect the taking sterilised enucleation equipment which is maintained in readiness, eyes have to be removed 10 hours of death to be suitable for optical grafts experience these melancholy occasions are treated with a sense of dignity and respect bereaved relatives, who derive consolation fro fact that the last wishes of the deceased are The only occasion on which umbrage has when it was not possible to comply with a because notification of death did not reach the in time and the relatives felt that they had faith

For administration purposes, and to arrange the admission of patients for corneal grafting to ervation of donor eyes has become an essential part his method of treatment At the present time the st suitable method of preservation beyond a few hours o bank the eyes in sterile antibiotic/liquid paraffin tions at 4°C in a refrigerator: such material is able for subsequent grafting up to 14 days after oval provided it is sterile

he sterility of cadaver donor eyes has become a matter reat importance as it has been found that about one d of such eyes have initial contamination by patho ic organisms and have to be discarded This wastage be checked by antibiotic preventive measures at the e of excision or before preservation The eyes or neas are well irrigated with penicillin solution before oval and are immersed in penicillin streptomycin ition before being placed in the eye bank. Control tures are taken at various stages of preparation and servation: a positive culture excludes the use of the for donor material.

n the Corneo Plastic Unit Queen Victoria Hospital, t Grinstead, the supply of donor eyes has been more n doubled since the Corneal Grafting Act became law it is still far from adequate for all purposes The ications of corneal graft surgery continue to expand l the selection of material and cases becomes more l more critical. As a result of these measures and the of improved material the standards of visual success steadily rising and about three quarters of those ients on whom a corneal graft operation is performed y expect improvement of vision in varying degrees to normality A recent valuable adjunct to the final ccess of corneal graft surgery is the use of the contact ses.

t is hoped that this summary may help to answer ie of the many inquiries which are received and it is ased that the collection of this valuable material has n much facilitated by the coöperation of the general titioner house-surgeon relations and ophthalmic geon

ndon, W 1 B W RYCROFT

## CHEMOTHERAPY OF LEPROSY

IR—Dr Lowe is to be congratulated on the good lts he has obtained with sulphones in treating leprosy astern Nigeria (Nov 20), but experience in treating disease in England prompts me to sound a less happy

atients of various nationalities are receiving treatment for omatous leprosy at the Jordan Hospital Earlswood ey they are principally Europeans and Anglo Indians, results with sulphone are unfortunately far from satis ory Although clinical improvement occurs first (thus uraging the patients to persevere with treatment) bacterio al improvement lags sadly behind Furthermore nearly y one of these lepromatous patients receiving sulphone had repeated reactions characterised by fever erythema sum neuritis arthralgia, and mental depression. The *essful management of such cases calls for considerable* cal experience.

feel sure that Dr Lowe would be the last to say that iks to sulphones all is well in the therapy of leprosy, the average reader of his paper may have gained the ression that the disease has finally been mastered rying to find an explanation for Dr Lowe s encourag results one must take into consideration the fact the leprosy situation in Eastern Nigeria is particu favourable for the disease has largely been brought er control by the system of clan segregation which instituted some twenty or more years ago This has ed the lepromatous rate to fall considerably leaving portionately fewer advanced lepromatous cases

his letter is written not to belittle the excellent work astern Nigeria but to dispel any attitude of com ency which Dr Lowe s paper may have engendered to warn readers that his results apply to Africans in a particularly well favoured part of Africa and are exceptional We have a long way to go in the treatment of leprosy and the need for more research into newer and better methods of treatment is vital and urgent

## PULMONARY EMBOLISM

SIR,—Your leading article of Jan 1 is timely in drawing attention to a much neglected cause of prolongation of invalidism and of a steady mortality among the middle aged and elderly

Thrombosis of the deep veins of the leg in elderly patients is commoner that many of us imagine If post-mortem figures are to be relied on, Hunter et al.[1] have shown that thrombosis of the deep veins is present in 52 7% of middle-aged and elderly patients confined to bed They also found that these thromboses are relatively silent until the unheralded catastrophe of a massive pulmonary embolus. In a series of post-mortems performed by myself in the past few years massive pulmonary embolism was the immediate cause of 20 (4·4%) deaths out of 448 In 18 of these cases the catastrophe followed on operation or accident

It seems that present-day preventive measures have failed Israel[2] affirms that great attention has been given to prevention of venous thrombosis by employment of early ambulation prophylactic femoral vein ligation and the use of anticoagulants. It is disappointing that studies indicate no reduction in frequency in thrombo-embolism has been achieved.

There is some evidence both clinical and laboratory that too much fat in the diet predisposes to clotting Fullerton et al[3] have shown that after a large fatty meal the prothrombin and clotting times are greatly reduced compared with the fasting times Other workers[4] have shown that a lipoid factor is essential for normal clotting but its precise character has not been determined

From the clinical aspect Dedichen et al.[5] have shown that in Norway the incidence of thrombo-embolic phenomena after operations liable to cause such complications fell very markedly during the German occupation They believe this was due to the reduced diet especially of fat the calorie intake fell from 3470 to 2840 per day and the fat intake from 159 to 71 g per day In Denmark, during the same period rationing was not severe and the incidence of thrombo-embolic phenomena continued as before

In view of the failure of present-day preventive methods it might be worth arranging a large inquiry to show whether a light low fat diet in the days after operation or trauma might not reduce the death rate and invalidism from pulmonary embolism

## REPAIR OF FEMORAL HERNIA

SIR,—In his letter of Dec 18 Mr Sandell makes a useful suggestion for the reduction of the sac in femoral hernia, but I notice that he advocates the Lotheissen operation Surely the method of McEvedy is to be preferred? And better than either in my opinion is the approach through a lower paramedian incision without opening the peritoneal cavity I have used this approach routinely since 1948 and find it extremely satisfactory but I have met few registrars or house surgeons who have seen it used

The rectus muscle is retracted to the appropriate side and with gauze—or better still with the fingers—the fascia in the hypogastrium and iliac fossa is gently swept backwards. The upper surface of Gimbernat s ligament can then be seen together with the disposition of the obturator vessels and the bladder Further gauze dissection exposes the hernia and one can usually predict the contents of the sac from its appearance and from the history With gentle pressure

---

Dr. Robert Heilig

below Poupart's ligament, and very gentle traction on the sac with gauze, judicious blunt dissection delivers the sac without cutting The most adherent part seems often to be in front, and there may be delay in freeing the sac from the deep aspect of Poupart's ligament—which is, however, clearly visible

The peritoneal cavity can, of course, be opened if, for any reason, that seems the safer method

I consider it unnecessary to close the upper end of the femoral canal, but this can be done easily by stitching Poupart's to Cooper's ligament As a rule there is remarkably little bleeding, and I have never seen a hæmatoma form in the thigh.

Familiarity with the space through which the operation is done is valuable, for it is the best approach to the prostate, a large portion of the bladder, the lower ends of both ureters, the obturator nerves, the proximal ends of the inguinal and femoral canals, the spermatic cords, and the external iliac vessels and lymph nodes The appendix and the female genitalia are also accessible if the peritoneal opening, made when the inguinal or femoral sac is cut off, is slightly enlarged , and it may be wiser to remove the appendix if there is anything odd about the pain ascribed to a right sided hernia

## SYME'S AMPUTATION

SIR,—It would indeed be unfortunate if, following Mr Shelswell's article of Dec 25, the profession were induced to try again Syme's amputation, which was relegated to the surgical scrap-heap thirty years ago, and if the lessons, so slowly and painfully acquired during and after the 1914–18 war, had to be learnt once again Soon after that war, the surgeons at Queen Mary's Hospital, Roehampton, of whom I was one, undertook a long and thorough review of Syme's amputation, in all its aspects I would emphasise that this review was done with absolute impartiality and we had no brief from either the detractors or the sponsors of the amputation, though the latter were far the more vocal Our findings were very definitely against the amputation, and in consequence it was accepted by surgeons, in this country, as obsolete Our reasons for condemning Syme's amputation were

(1) Less than 40% of the original Syme's amputations under review had been capable of taking full end bearing Most of the cases unable to take full end bearing had had reamputation through the middle third of the leg and the vast majority of these reamputees had expressed the opinion that their efficiency had been increased, in greater or lesser degree

(2) Secondary operations on the stumps of Syme s amputees —e g , excision of scars, neuromata, &c —were almost invariably " failures "

(3) The amputation was quite unsuitable, for æsthetic reasons, in women For the same reason, though to a much lesser degree, it was undesirable in men

(4) The prosthesis for a Syme's amputation necessitated a leather socket which is not as comfortable as willow or duralumin Further, the leather socket has other disadvantages —e g , smell, prevention of evaporation of sweat, &c

(5) The " wear and tear " of a Syme's prosthesis was much greater than of the ordinary below knee leg

(6) The gait of the Syme amputee, with his prosthesis, was ungainly as compared with the below knee amputee

(7) The functional efficiency of the below knee amputee, with a good stump, was slightly better than that of the satisfactory Syme amputee

Perhaps our greatest difficulty in persuading the sponsors of Syme's amputation of its unsuitability was to convince them that, although the stump which they had fashioned so admirably might appear so wonderful to them, this was really no criterion at all

If the matter is pursued, no doubt we will again have the old arguments adduced that the limb maker should make his prosthesis for the stump, not the the stump for the prosthesis , that many of the original Syme's amputations were faulty because technique, or that they were done with improper tions (e g , frostbite) , that the stump which ca full end bearing must be the ideal stump , that Syme's prosthesis is cheaper than the below kne thesis , and so on All these arguments were ca considered by us at the time, but we were in no about our final judgment against the Syme

The fallacy of Mr Shelswell's investigations he has taken the residual " less than 40% " sati Syme's amputees and has proved that 66% of th satisfactory This means that about 26% of the Syme's amputations continue to be satisfactory— a reason for resuscitating a discredited operation.

## TRANSHEPATIC CHOLANGIOGRAPH

SIR,—The Association of Surgeons at its mee Glasgow next April is to discuss diagnostic proc in obstructive jaundice I have been asked to c information about preoperative transhepatic chol graphy—a procedure not often carried out—and I be grateful if any of your readers who have had *ence of it would let me have a brief account* of results, including particularly any complication

121 Harley Street
London W 1

DAVID H PA

## MERIT AWARDS

SIR,—The M D B circular no 19, concerning proportion of distinction awards payable to c teachers and research-workers holding honorary ap ments, to which you referred briefly on Dec 25 (p must restrict the scope of research that is to be taken by such men The fraction of the award no paid is to be based upon the number of hours sp strictly clinical work, and time spent upon resea to receive financial reward only if it is " spec related to the diagnosis and treatment of indi patients " (my italics of an important word which omitted in your report) This restriction on the pa of distinction awards gives whole time clinical re workers a financial incentive to neglect the deve of new diagnostic or therapeutic measures which first be studied at the laboratory bench or upon They will only be paid the whole of any award t they are entitled if they either restrict their well established procedures or if they try out t *operation*, the *new drug*, the *new catheter*, an directly upon patients even though preliminary tory study is necessary ! Nor can these res consider any extension of their interests into pre medicine without financial loss The man, for who tries out well-known palliative treatment victims of smog will get his award in full, but man who decides to investigate the effects of atmospheric pollutants on the respiratory tract to guide preventive measures, or even to dev efficient respirator to protect individuals befo become patients

Distinction awards were, of course, originally duced as a recompense for the loss of income from practice which consultants in the N H S were e to suffer, so that it is logical to allocate them in to time spent in clinical work , but this is da logic, and the decision to make whole time ac clinicians fully eligible for the awards was a pro step towards the recognition that those who cult tree of clinical science deserve at least as great as those who garner its fruits The new regulat retrograde step, and if it is strictly applied it mu harmful influence upon the development of research in this country

Richmond Green,
Surrey

## CURRENCY FOR TREATMENT ABROAD

IR —Since the war it has been necessary to restrict use of British currency abroad and seven years ago Exchange Control Medical Advisory Committee was up to deal with applications by patients advised to medical treatment overseas No one in the Govern t or otherwise liked the idea of restricting facilities l for health and the responsibility of allocating ign exchange on medical grounds was entrusted to a lical committee with the duty to safeguard the rests of the patients, as well as conserve so far as sible our limited foreign exchange

t is the Government s policy to simplify exchange trol procedure and in future the patient s bank will authorised to grant foreign currency solely on the ngth of a doctor's recommendation that it is required medical grounds Banks will provide a printed n but the doctor may write his own certificate vided similar wording is used

When currency is required for the United States of erica or Canada, the patient s doctor will be asked to ify that the dollars are required for medical or gical treatment which cannot be obtained elsewhere

he Exchange Control Medical Advisory Committee ld like to take this opportunity of thanking their lical colleagues all over the country for their patience forbearance The doctor has generally had the cate responsibility of deciding whether he ought to port a patient s desire to go overseas or whether tment at home would be equally satisfactory lging applications has not been easy but the committee happy to think that even in the most stringent ncial period over 75% of applications were granted, during most of the committee s existence more than Few if any sick people in genuine need of treatment h could not be obtained in this country or the ling area have been unable to obtain it

## VENEREOLOGY AND DERMATOLOGY

R —Mr King and Dr Russell (Jan 1) consider the nt advertisement of a combined post in venereology dermatology to be a retrograde step I would like omment because I worked in that East Kent area n 1938 to 1946 and also because I happen to be one he few consultants permitted to practise both alties since the National Health Service began

e incidence of venereal disease in East Kent would nsufficient to hold the interest of a venereologist s he were also attached to a larger centre and my own experience that entails a great deal of elling and waste of time Furthermore clinical rial and facilities for research—the life blood of mbitious specialist—are not always available in a rural area but many good clinicians do not aspire is

principle I am in favour of the separation of these alties although in many parts of the world they are combined We should however guard against too n specialisation : there is still room for the general eon and consultant physician as distinct from the alist there are difficult cases where the broader is sometimes of value A special knowledge of atology is often useful to the venereologist and versa secondary syphilis has been diagnosed as onamide rash by a dermatologist and psoriasis een unrecognised by a venereologist

ny consultants have a competent knowledge of both lties My senior registrar in venereology holding a joint ntment with another hospital (I understand he is not plicant for the post in question) has, as a result of the suggestion of a ' pure dermatologist at the selection committee also worked regularly for three years in the skin departments of both hospitals

However good the separation of these subjects is in principle there are exceptions to every rule and the conditions in East Kent are in my opinion an example of one such instance It is surely better to offer the right man adequate employment so that both specialties are adequately covered than to appoint two men who might stagnate and find outside interests Some specialists give much time to committee work or politics I fail to see why utilising this spare time in another medical interest is a retrograde step

London W 1

DAVID ERSKINE

## MEDICINE IN THE SOVIET UNION

SIR —Dr Fox s broadcast not only raised points of interest with regard to upbringing and its results in the U S S R but also invites comparison between planned methods of training of children and our own laissez faire It may be profitable to consider further the three types of community to which Dr Soddy refers in his letter of Dec 25

Neurosis, in all its manifestations has a double origin It arises first from unresolved dissatisfaction in the early parent-child relationship but its second cause equally important is the strain put on the individual by the outside world which makes demands different from his expectations Fear and dissatisfaction then work on his inner structure and produce the symptoms

In the wholly planned community the first emotional relationship is likely to be different from ours only in so far as the parents may have more economic security though perhaps if the individual fits the ideal picture prevalent in that culture he will have special reason to feel confident Any deficiencies in this early relationship however may never become manifest because of the continuity in the framework within which the individual lives From the earliest age conformity is demanded and security given in return The love instincts may or may not be satisfied but the child s hate is distributed on to others ' whom he may indeed be required to hate Provided he is no rebel—and the large majority of humans are conformists—he need not come into conflict with an outside world which differs from his expectations and he is thereby saved from neurosis.

In the type of community the U S A represents the child is reared at first in an intensely individual atmosphere This is followed (as Dr Soddy points out) by an equally intense training in group relationship and loyalties Finally he enters a fiercely competitive workaday world which brings him into conflict both with his early ethical teaching and with his group identifications This conflict is the crux of the tension and anxiety which is produced

In our type of morality the bonds are intense at first, but the group does not wholly replace family influence nor is the adult world based entirely on competitive success values Nevertheless the individual has almost always had an imperfect relationship in the home and the very looseness of the bonds and the variety of choices and expectations are also likely to induce conflict There is a crisis aspect of childbirth—partly economic—which evokes anxiety in many homes. This is transmitted to the child as well as the uncertainties caused by the absence of a stable broad synthesis. Very few people are able to achieve such a synthesis by the time they are physically fit and able to have children

During the last 50–70 years our larger ethical framework has collapsed and its collapse has deprived us of pegs on which to hang our standards. It has also led to a piecemeal revision of our methods of upbringing and education which has put a very great strain on the individual Though we have advanced beyond the stage where a ready-made pattern, of supposedly universal validity, would satisfy us, we are far from giving the individual the strength he needs to enable him to get satisfaction from his world, nor have we tried to remove inconsistencies from his thorny path, or prepared him from his childhood onwards to meet the world's expectations to the best of his ability To my mind, this is the explanation of our higher breakdown-rate, which is therefore to some extent preventable As a nation we are, in the eyes of the outside world, rather more secure than we have been for some time past, and it is now up to us to fit the individual better for his task In particular, we must enable him to grow up better equipped emotionally and to have continuity in the demands made on him

Roehampton, London, S W 15 HEDY SYMONDS

## BED-WEIGHING MACHINE

SIR,—In work on changes in metabolism of water and electrolytes after injury we were concerned with obtaining accurate daily weights of patients, most of whom were bedridden and some of whom were being treated with Sinclair traction apparatus There was at that time no suitable bed-weighing machine in this country, though a Swedish model had been described [1], so, while awaiting completion of the Avery (33N) machine described by Darmady,[2] we experimented with a modification of a personal weighing-machine

A steel trough was attached to the platform to accommodate the two castors of one end of a hospital bed so that each end of the bed could be weighed separately, the end not being weighed was raised with wooden blocks to the level of the platform The accuracy of this method —and later that of the bed-weighing machine (type 33N)—was tested by repeated weighing of beds with and without occupants When satisfactory techniques had been established, different patients and beds, with and without Sinclair traction apparatus, were weighed With both methods of weighing, the beds were lowered to the ground after each observation, in this way each bed was weighed ten times The accompanying table summarises the results and gives the standard deviations calculated from the serial weighings

The improvised method was found to be insufficiently accurate for following daily changes in the balance of water, but the bed-weighing machine proved entirely satisfactory for this purpose It will be seen from the table that with the bed-weighing machine the error is virtually independent of the absolute weight being measured, and that changes of more than about 50 g based on single readings have less than a 5% chance of being due to error in weighing Greater accuracy be obtained if on each occasion the mean of weighings is taken

| Method | Mean of ten weighings (kg) | | | Standard error (g) | |
|---|---|---|---|---|---|
| | Mean total weight | Bed only | Patient only | Single observation | Mean of ten weighings |
| Improvised bed weighing machine | 144 790<br>151 750<br>146 400<br>206 680<br>90 375<br>81 720<br>75 670<br>68 760 | 90 430<br>90·540<br>90 355<br>140 030<br>90 375<br>81 720<br>75 676<br>68 760 | 54 360<br>61 210<br>56 045<br>66 650 | ± 2896<br>± 3280<br>± 3260<br>± 2599<br>± 1616<br>± 1961<br>± 1835<br>± 1629 | ± 916 4<br>±1038 5<br>±1031 9<br>± 822 1<br>± 511 4<br>± 620 6<br>± 580 8<br>± 515 0 |
| New bed-weighing machine (type 33N) | 192 266<br>126 544<br>191 076<br>227 680<br>146 142<br>78 805<br>82 644<br>72 544 | 123 486<br>65 284<br>121 026<br>122 260<br>78 805<br>78 805<br>82 644<br>72 544 | 68 780<br>61 260<br>70 050<br>65 420<br>67 337 | ± 23 1<br>± 27 2<br>± 27 8<br>± 16 8<br>± 27 8<br>± 22 8<br>± 16 8<br>± 16 8 | ± 7 3<br>± 8 6<br>± 8 8<br>± 5 3<br>± 8 8<br>± 7 2<br>± 5 3<br>± 5 3 |

## RENAL CHANGES IN ECLAMPSIA

SIR,—As a survey, your annotation of Dec. disappointing because it fails (a) to take acc the researches of Oliver [1] and Sheehan [2], (b) to re that the release of thromboplastin cannot be an es ætiological factor in eclampsia, (c) to relate G findings to similar findings in cases of hyperte (d) to weigh the evidence which denies the a corticoids a *primary* ætiological importance, and appreciate the rationale of modern therapeutic n

In Oliver's *original investigation* on the kidneys by Shaw Dunn [3] *from cases of obstetric* anuria ( eclampsia), considerable necrosis of the renal cortex, survival of the juxtamedullary area, was apparent Wh nephron dissection was *undertaken, the damage* appe be due to an altered vascular state rather than to a Sheehan's extensive series of anuric (including post-e kidneys showed lesions which *could only have* been spasm of the intralobular arteries Thus both thes attribute the renal condition to ischæmia

McManus [4] says that in acute hypertension the arteries of interlobar size "show a marked thickening intima in a concentric laminated fashion" The gl shows proliferation of epithelium and endothelium, wit proliferated epithelial cells of the visceral layer bec filled with large colloid droplets, and the tubules are d and lined by enlarged cells full of colloid droplets C notes that in eclampsia the afferent glomerular artery eccentric subendothelial deposits, there is increased larity of the glomerular tufts with formation of droplets intercapillary space, and the proximal convoluted show cloudy swelling and contain albuminoid débris ing for differences in interpretation, both these author to be describing much the same condition If in McM cases this was known to be the result of a raised blood why should it be attributed to a different cause in C

There is no evidence that in the 12 pregnant w Govan's series who were free from eclampsia, or renal disease the renal vessels had not during p been subjected to hypertensive factors which had rai pressure above its pre pregnancy level

As adrenocorticoids have not been demonstrated to in amount pari passu with the increase in toxæmia— they actually decrease as pre eclampsia mounts unlikely that they are primarily responsible for the *manifestations Moreover the potassium loss pro* adrenocorticoids, accompanying sodium retention, is in pregnancy toxæmia [6] To induce hypertension the *corticoids require a great excess of sodium,* and prophylactic restriction of salt should—at least in th deprive them of such an effect No hormonal hyp could explain why the primigravid are peculiarly eclampsia The toxæmia like effects which you men having been produced in rats by injection of posterior p extract could well be due to renal ischæmia, which h shown to occur by Trueta et al.[7], for, in rats deoxycortone and sodium chloride,[8] similar effects res injection of renin—a substance proved to provoke ischæmia.[9] Byrom [10] also has produced an eclamp state in rats by inducing renal ischæmia with the Go clamp

*It* is renal ischæmia that the experimental, clin pathological evidence incriminates, and the ther lence points in the same direction The success obtained hypotensive drugs can be explained by their increasing l blood-flow Likewise dramatic improvement in mpsia occurs when conduction anæsthesia reaches the l of the lesser splanchnic nerve[11] thereby reducing the vous impulses responsible for renal ischæmia

[10] Byrom, F B *Lancet* 1954 ii, 201

n your leader on anuria (Dec 11) you have equally rlooked the ætiological significance of the spasm of renal cortical vessels although you have indicated its dence in the four clinical types described. This ulatory change in anuria has been combated very cessfully by the Dublin school of obstetricians in way which incidentally elucidates the pathological nges responsible for anuria Over the past two years Feeney[12] and Dr Barry[13] have demonstrated the ue of splanchnic block in incipient and early estab led anuria complicating concealed accidental hæmor ge (which you recognise as the most formidable com ation of circumstances) They have also lent support my thesis by recording improvement following rupture the membranes in that condition

It will soon I believe be clearly evident that eclampsia d the anuria it produces, are the result of a renal tical ischæmia provoked by the resistance of the rometrium to stretch

ondon W 1  JOHN SOPHIAN

## MENTAL CHANGES AND ORGANIC DISEASE

SIR,—I have read with interest your annotation of v 13 on this subject.

I would point out that we did not say that the ychiatric diagnosis was abandoned after localised normalities had been found in electro-encephalograms ther we wished to emphasise the presence of an ganic lesion in addition to the psychiatric difficulty e were and continue to be concerned about the nbers of patients who do have organic disorders of central nervous system and in whom the presenting ptoms are primarily psychiatric

am unable to understand the last phrase of your ment ' *but its routine use as recommended by* ggoner and Bagchi is likely to give rise to other gnostic mistakes ' Certainly this is not a valid ment if the electro-encephalogram and clinical studies properly evaluated

uropsychiatric Institute
University Hospital
Ann Arbor
Michigan U.S.A  RAYMOND W WAGGONER.

* It was the likelihood that routine use of electro- phalography in mental hospitals might *not* always accompanied by adequate evaluation of clinical and tro encephalographic studies that gave rise to our ment —ED L

## REACTIONS TO IODISED OIL

IR,—For thirty years almost every week I have doing hysterosalpingograms probably well over ) In 90% of these iodised oil has been used in water-soluble dyes In my own mind I have no bt that the advantages obtained in the 90% from point of view of diagnosis and therapeusis have outweighed the very small risk of experimental ulomata referred to by Mr de Boer in your issue of 25—a condition which I am prepared to admit it occur if the tube be obstructed at the fimbria mpulla But should a tube be found so pathologically ed using either solution I would remind him that chances of surgical success or natural recuperation certainly under 15% Moreover he will readily l that it is the very commonest of surgical findings e the convolutions of a small tortuous hydrosalpinx closely adherent and kinked—properties of minor obstruction by no means solely confined to the oviduct of Fallopius

Those who run fertility clinics are generally agreed that after an intimate history has been taken a Rubins $CO_2$ test is the first line of investigation. Only should this be doubtful or negative is recourse had to an oil test for if there is no clinical question or palpable doubt that the case is one of primary sterility or for that matter a clean case of secondary sterility then I am confident that iodised oil used gently and meagrely under the keen screen control of a radiologist, is best Moreover in such a case I believe it is just because of the nascent iodine that such a technique is so often of great therapeutic value for it is quite phenomenal to see and hear of the number of patients who have conceived immediately after the use of iodised oil If however there is a history (not so very common these days) of tubal infection or febrile salpingitis there is perhaps some reason for the use of water soluble radio opaque material, though even here the transient fluffy smog like shadows, at the end of the tubes are often difficult to interpret On many occasions when such cases have failed to conceive or have undergone further investigation it has been shown at laparotomy that the tube so happily diagnosed as patent because of an immediate fog of material at its end is in reality a tube and ovary surrounded by mosquito-curtain like veils of peritoneum absolutely inhibiting exit or entry of the ovum.

At the Royal Society of Medicine I was speaking of cornual occlusion of the tube secondary either to criminal abortion, induced abortion or postpartum infection Repeated $CO_2$ and oil tests demonstrate that in 95% of patients giving such clinical histories where there is no palpable abnormality whatever the blockage is never beyond the isthmus but confined to the cornu and interstitial portion of the tubes

In such cases there is no question whatever that a clean-cut iodised-oil picture is an essential prerequisite to surgical intervention subsequent operation always demonstrating that the distal portion of the tube is abolutely healthy and therefore readily implantable Such a picture can never be obtained by the usual hazy dyes, though the new material Salpix may prove to be the exception

London W 1  V B GREEN ARMYTAGE

## RECOGNITION OF TABLETS

SIR —Manufacturers might use a system of code numbers to help doctors to identify by sight those tablets they have previously prescribed A simple system of duplicate records might however prove less unwieldy in the long run It would be virtually impossible to carry any code beyond the range of the proprietary tablets To consider the extreme case hospitals now often compress certain tablets to meet their own needs specially made punches and dies would certainly not be forthcoming to codify such tablets Moreover an established drug (for example phenytoin sodium) will often masquerade as a plain tablet marked tablet sugar-coated tablet or capsule In such circumstances the only sure guide is chemical identification

The scheme of identification I have outlined[1] has been elaborated to meet the needs of a busy hospital, and has proved perfectly workable It is quite true that time care and some apparatus are required for the tests—especially care But although the reagents are unstable the components may be stored for a month or more without prejudice to the reactions Fresh reagents are an important safeguard against false negatives which would be very misleading Compound tablets are not quite so baffling as you suggest in your annotation of Jan 1 The main toxic ingredient can be detected almost invariably within the ten minutes allowed and the rest of the tablet can then be investigated at greater leisure As in any simplified scheme there are notable

Southmead Hospital Bristol
PETER COOPER

SIR,—We were interested in your suggestion that manufacturers should consider stamping tablets with code numbers It has long been our practice, and we believe also of some other companies in the industry, to emboss tablets with a distinctive mark A list of our tablet markings is available on request to any doctor who would like to have it

There is a feeling amongst some pharmacists that it would be better if tablets were more uniform in size, shape, and colour and if sugar coated tablets, for instance, were all white Whilst we believe this might have some advantages to the retail pharmacist, we think it would be less convenient to the medical practitioner Apart from the urgent problem of identifying a possible cause of poisoning, there are many other occasions when it is useful for a doctor to look at a tablet and to be able to immediately identify it by a mark or other characteristic with which he is familiar

## AGAMMAGLOBULINÆMIA

SIR,—I hesitate to prolong this discussion, but I feel I must correct one or two statements made by Dr Bowley and Mr Dunsford in their letter of Dec 11

They state that no query would have arisen had I advised Dr Grant and Dr Wallace that I had used βα in the examination of the group Yet I did say that Dr Grant and Dr Wallace used only part of my report I had, of course, advised them of my investigation, but they had every right to make use of my report in part or in full, as they thought fit They emphasised the pathological and clinical aspects of the case, because these were of more general interest than the serological investigations I assumed (as it turned out, wrongly) that my colleagues would realise that where blood grouping is performed on many thousands of samples, it is usually done by people who know something of the subject I am pleased that my findings are now acceptable

I was not in fact surprised when we found α missing I suspected some serological abnormalities when Dr Grant first presented the case at a local scientific meeting, and I therefore asked permission to perform the serological investigation I am sure Dr Bowley and Mr Dunsford are very familiar with the extensive literature on the location of the β and α agglutinins in the plasma, so they will know that these two agglutinins are located in the gamma fraction [1] I am therefore certain that had they been presented with such a clear-cut case of agammaglobulinæmia, they would not have been surprised at finding serological abnormalities

Concerning secretion of group-A substance, I did know of the paper by van Loghem [2] to which Dr Bowley and Mr Dunsford refer, what I said was not that I could not find any paper which showed that people of these subgroups of A did not secrete group A substance, but that "I was not able to find any literature supporting their dogmatic statement" The paper by Grove-Rasmussen et al [3] (which they themselves quote) says that the saliva of the donor K7332 inhibited group O serum when this was tested against his own cells which surely means that the donor secreted in his saliva something which, Dr Bowley and Mr Dunsford must admit, behaves very much like group A substance

In their last paragraph they say "A study of th
will show there are marked differences between A$_4$ and
Undoubtedly the literature must be studied, but
scientist should read with discrimination Uncritical
tance of everything published often creates confus
confounded I think they will agree that we have had
of confused terminology in hæmatoserology, and I therefore refer them to some parts of the literature where
differences do not appear so very marked For ins
Grove Rasmussen et al [3] say "Dunsford refers to a
blood studied by Gamelgaard and Marcussen but app
term A$_4$ for this type of blood The term A$_0$, however
preferable because it is more descriptive of its
behaviour with Group O serums " Again, Race and
in their latest edition of *Blood Groups in Man* say (p
"van Loghem and van der Hart have found thr
(*synonyms $A_x$ and $A_0$*) children " (*my italics*)

All this has really nothing to do with the
paper by Dr Grant and Dr Wallace, and I hope
Dr Bowley and Mr Dunsford will agree that
controversy should now end

Birmingham

## SHOE DESIGN AND TOE DEFORMATIO

SIR,—Professor Haines and Mr McDougall (Dec 25)
further proof of the bad design of the footwear of
adult and adolescent They rightly state that "Ideal
pressure on the toes should be avoided" and it is
cant that it is always this feature of design that i
first to be modified or abandoned *Satra Bul*
reporting on the adoption of their "ideally" de
lasts for children, comments [1] that "several firms
adopted lasts modelled by us Others have re
minor modifications, especially in toe shape."

Professor Haines and Mr McDougall may be wrong
they say that "the modern male track runners' spiked
has to be somewhat pointed and very tight over the
give the grip required" It may indeed be designed
way and these features may be essential to "fit" that
of footwear, but, I submit, shoes for this purpose
accommodate the feet so that they function as natural
as efficiently as possible Observe the feet on the
runner and you will find he seeks the maximum
contact for his toes, thereby getting the best possible
As I have suggested elsewhere,[2] shoes designed on the
by adding to the efficiency of the feet might well knock
off track records

Professor Haines and Mr McDougall also state "th
design of most shoes for adults "must necessarily d
however well fitted." This statement will appear
dictory to many readers who believe, as I do, that you
"fit" a badly designed shoe The term "fit," howev
become so ambiguous and so widely used by the
of shoe reform that its use is dangerous and its m
capable of gross distortion

All foot surveys to date have carefully avoided
consideration of shoe design all faults of design
been included in the classification "a short fit" or
fitting"—which are both terms implying that th
no fault of design but faults of selection by pur
or retailer

This of itself may not seem important but, as I
already shown,[3] such things affect Government
and a study of the latest report from the Min
Education [4] confirms this view In support
complacent attitude the Ministry quotes twice
page references to reports stating there is no corr
between foot deformity and shoe fitting There
mention of shoe design nor of the fact that it is imp
to obtain factory-made shoes that will not deform
of school leaving age No doubt many parents
delighted to hear the news given in the report th

h of the country s children was everywhere satis ory but those of us interested in children's feet no grounds for satisfaction and we deplore the ent attitude of the Government

present no factory made shoes are available for ts or adolescents that avoid all pressure on the ' The shoes available are not only producing much rmity but also preventing correction of existing rmities Surely this is a matter requiring the urgent ation of the Minister of Health

ndon S E 15 CHARLES A PRATT

R —Having advocated a straight inner border to otect the great toe from excessive deviation Professor nes and Mr McDougall add but unless other stments were made to resist it the pressure on lateral toes would be unbearable" It may be d

Is not any deviation of the great toe excessive ?

Why if the shoe is designed to fit the foot, and pressure fore taken on the heel and instep should it be assumed there is any pressure on the lateral toes—let alone an arable one ?

Surely in the sentence containing the words "the bad n of most shoes for adults" *all* should be substituted for ?

## PTIC ULCERATION IN SOUTHERN NIGERIA

R,—The article by Mr Konstam in your issue of 20 was of particular interest to me since I have ated on 16 cases of acquired pyloric stenosis in ans living in the south-east province of Sierra Leone e past two years All gave a long history of epigastric with symptoms of advancing pyloric stenosis and e majority the stomach was huge—even in a boy who was the youngest in my series. All were treated astrojejunostomy except one on whom partial ectomy was performed

their clinical features and the striking success of e operative measures my cases closely resemble the scribed by Mr Konstam But my operative findings significantly In all my patients there has been a loric mass of granulomatous tissue often ulcerated o centre Smears taken from the surface of this shown the ova of *Schistosoma hæmatobium* in nearly the cases and the appearance has resembled the ror of the urinary bladder in advanced bilharzia of organ Mr Konstam s cases revealed a state of ic duodenal ulceration with extensive adhesions d My experience has also been that adhesions ery dense and extensive and involve the pylorus luodenum with neighbouring organs On several ions I have found *S hæmatobium* ova in these ions and in the free peritoneal fluid There is a *resemblance between the adhesions found in this* ion and those seen in bilharzia of the female organs

istosomiasis is hyperendemic in this region the e being either active or latent in almost all the ation from the age of five or even younger onwards uspect that infestation with hæmatobium (far from ing its clinical manifestations to the urinary tract) both widespread and serious lesions in many parts body From the few cases of pyloric stenosis I so far treated it is impossible to draw conclusions is perhaps permissible to suggest that this con —in this country—is often a late result of a heavy ation with hæmatobium It would be interesting to whether this or other helminths commonly invade all of the stomach in the people of Southern a

# Obituary

## CHARLES JENNINGS MARSHALL

M.S M D Lond., F R C.S

Mr Jennings Marshall senior surgeon to Charing Cross Hospital died at his home in London on Dec. 29 at the age of 64

The son of C W Marshall, he was born in Cardiff and was educated at Cardiff High School. From Charing Cross Hospital Medical School he graduated M.B with honours in 1912 and was awarded the gold medal of the University of London After holding house-appointments at Charing Cross he took his M D in 1914, and while holding the post of surgical registrar the F R C.S. in 1915 The following year he gained the degree of M.S and again carried off a gold medal

The same year he accompanied his former chief Sir Herbert Waterhouse to Petrograd to join the staff of the Anglo-Russian Hospital which had been set up as a gesture of good will to our allies. Jennings Marshall served the hospital as assistant surgeon, and on his return from Russia he joined the R.A M C and was posted to Salonika

After the war he became assistant surgeon and junior orthopædist at King s College Hospital, but he gave up this appointment when he was elected to the staff of his own hospital He also joined the staff of the Victoria Hospital for Children, Tite Street where he had charge of the orthopædic department For many years he was a surgical consultant to the Ministry of Pensions and to the London County Council, He was an examiner for the universities of London and Manchester During the late war he was director of the surgical section of the Sutton Emergency Hospital

As a surgeon his interests and his experience were wide After the 1914–18 war he continued his work in orthopædics, notably at King s and at Tite Street, and in 1921 he described in our columns with verve and insight the arm training centre at Roehampton But he was in fact a general surgeon Though his monograph in 1938 was entitled *Chronic Diseases of the Abdomen* he pointed out that in his view the abdomen extends at least from the knees to the eyebrows. The racy style based on shrewd observation was typical of his teaching and his practice His other writings in collaboration with colleagues include *Textbook of Surgical Pathology* and *Textbook of Surgical Anatomy and Physiology* He wrote less than he might have but many of his unpublished practical innovations will live in the practice of his students. His friends at the Savage Club will also recall his self made receiving-sets in the early days of wireless, and his delight in music and the arts.

Mr Jennings Marshall married Miss Hope Embleton Smith who survives him

## HARALD NORRIS WEBBER

M.A., B Chir Camb F F.A R.C.S

Dr H N Webber consulting anæsthetist to University College Hospital, died in London on Dec 24 at the age of 73

The elder son of W H Webber of Brighton he was educated at Brighton Grammar School and at St. John s College Cambridge He continued his medical studies at University College Hospital qualifying in 1912 On the outbreak of war in 1914 he joined the R.A.M C., in which he reached the rank of major While serving in Egypt he nearly died from a severe attack of typhus fever

After the war he held house-appointments at several London hospitals and he became resident medical officer first at the West London Hospital and later at University College Hospital In those days this appointment carried with it the task of administering the anæsthetics for emergencies and in this way Webber s interest was aroused in the subject which was to become his life s work. In the early 20s he was appointed assistant anæsthetist to the hospital and towards the end of the late war he reached the position of senior anæsthetist He also served on the staffs of St Paul s Hospital and the Royal Hospital for Diseases of the Chest

His published work included papers, with the late W H R Rivers, on the action of caffeine and alcohol on the capacity for muscular work He was co-editor, with the late F S Rood, of a textbook on *Anæsthesia and Anæsthetics* He held office as president of the anæsthetics section of the Royal Society of Medicine, and in 1948 he was elected a fellow of the Faculty of Anæsthetists of the Royal College of Surgeons He was also a senior fellow of the Association of Anæsthetists

C W M writes "Webber was a cheerful and reliable colleague, always ready to lend a hand in the working of the hospital, to whose welfare he was wholeheartedly devoted, and in whose service he never spared himself He could always be counted on to give a safe and skilful anæsthetic During the late war he was twice bombed out of his home, but he refused to quit London and throughout the blitz he continued to serve in the section of the hospital detailed to attend to casualties On his retirement from U C H he took over the duties of resident medical officer at St Luke's Hostel for Clergy, and up to the time of his last illness he gave them unstinted help To his colleagues he leaves a memory of a life-time of hard work, well and truly done"

Dr Webber married Madeleine Mary, daughter of Major J J Ryder, who survives him

## ROBERT STIVALA ASPINALL

C I E , F R C S E , Lieut. Colonel I M S retd

Lieut.-Colonel Aspinall died in a London hospital on Christmas day, at the age of 59 At the outbreak of the 1914-18 war, he was a medical student at Guy's Hospital He served for a time in the ranks, but later returned to his studies and qualified in 1916 He then took a commission in the R A M C , and he was wounded in action in 1917 while serving as a regimental medical officer in France In 1922 he joined the Indian Medical Service, and after only two years in the military division of that service he was selected for employment in the foreign and political department, where he spent the rest of his service

For some years he was the chief official practitioner at Delhi and Simla, the winter and summer capitals of India, and he was a notable success in both appointments In 1929 he became F R C S E , and in 1936, while still a major, he was appointed C I E During the greater part of the late war, as residency surgeon, Mysore State, he was stationed at Bangalore, the headquarters of the Southern Army The enormous increase in the civil and military population of Bangalore greatly added to the clinical and administrative work of this appointment, but Aspinall coped with it all with great skill Just before the transfer of power in 1947 he was selected for promotion to the post of inspector-general of civil hospitals in the Punjab

Shortly before his last illness he had remarried and settled in practice in the West End of London He leaves two sons by a former marriage

A colleague writes "Robbie Aspinall was well equipped by nature and study to deal with any professional or social emergency A clubbable man with a host of friends in London and all over India he will be much missed"

## ANDREW DEUCHARS

M B Glasg , D T M &H

Dr Andrew Deuchars, resident medical officer at Stonehouse Hospital, Lanarkshire, died on Oct 16 After graduating at the University of Glasgow in 1946, he was house-physician to the late Prof Noah Morris at Stobhill Hospital, Glasgow Later he served with the R A M C in Palestine, East Africa, and Mauritius In 1949 he became house-physician to Dr David Smith at the Royal Infirmary, Glasgow, and the following year he took his D T M & H. at Liverpool In the same year he was appointed junior hospital medical officer at Cleland Hospital, Lanarkshire, and soon afterwards took up his appointment at Stonehouse Hospital

T S C writes "When I first met Dr Deuchars, I was at once impressed by his attentive and thoughtful poise of mind It was in the clinical realm that I came to know his familiar presence so well and to feel the reinforcement of his able assistance He was one of those young men who did not fail to appreciate, from the ical standpoint, the full opportunities offered by overseas, especially in a tropical zone A keen ob he brought home much, to the enhancement of his acumen During the four years of his appoint Stonehouse Hospital the full promise of his men attainment became manifest The relief of the evening hour was a province which was part his own, and he was held in high esteem by all who had known his touch"

## Dr ELIZABETH CASSON

G de M R writes "The residential clinic Dr Casson founded at Dorset House, Bristol, patients who were only able to afford modest Later she extended her work by taking on the Pleasant nursing-home at Clevedon, Somerset, by the beginning of the war in 1939 she had 100 patients Owing to bombing, she moved the House clinic to Clevedon, using two more houses. she continued the principle of low fees and at admitted patients without charge She spent he herself, and she financed the Dorset House Sch Occupational Therapy in its beginning Indeed years passed before it was able to run at its level without financial help from her"

## OXFORD PLANS

the first half of their master plan for the development Radcliffe Infirmary site the board of governors of the d Oxford Hospitals on Dec 29 approved plans to provide accommodation for the Medical School of the University

board have agreed to provide 50 beds and laboratory accom tion on the Infirmary site for the Nuffield professor of medicine 50 beds and laboratories for the Nuffield professor of surgery ed and more suitable accommodation and workshops for the sor of anæsthetics; 25 beds and laboratories for a new regius sor of medicine who will be a clinician a new biochemistry tment considerable extensions to the pathology laboratories small extension for the department of radiology

e Ministry of Health have approved this whole plan in iple and the first part of it in detail, and are prepared to a financial contribution. The cost of these buildings no more than £400 000, and something over £200 000 will from university sources."

e second half of the master plan which has also been oved in principle by the Ministry of Health gives much d additional wards and departmental extensions. The rsity has agreed to give the same wholehearted support e rest of the plan (though it cannot give financial support) has given to the first instalment for the benefit of the cal school The board and the university are well satisfied these joint arrangements and are grateful to the Ministry alth for their interest and support

## ACCOMMODATION FOR HOSPITAL STAFF

Ministry of Health memorandum to hospital authorities[1] rks It has been represented to the Minister in the se of discussions he has had about the current shortage of r hospital medical staff that the provision of more resi ial accommodation by hospital authorities would con ite to the solution of this problem. The memorandum ves that the powers to provide residential accommoda conferred by the National Health Service Act are only ary to the main duty of providing hospital services; o these powers can appropriately be exercised only when essential to the proper conduct of the service Secondly not necessarily in the interests of the staff themselves they should live in accommodation provided by the al authority for hospital staff only Thirdly in view of tions on capital expenditure as little money as possible d be devoted to acquiring or building residential accom tion Accordingly hospital authorities should consider ling residential accommodation whether by purchase conversion new building or the allocation of existing modation only: (1) where the staff in question must o nature of their duties live on or near the hospital where the hospital is remote from any housing develop and no other suitable accommodation is obtainable in cality Where these criteria are satisfied married rs may also be provided for married staff Whether or hese two criteria are satisfied hospital authorities can aff to get houses, flats or rooms in other ways including proaches to local housing authorities and other land to obtain sympathetic consideration of requests by the question for rented accommodation and (*b*) maintain list of suitable flats &c for the information of those eed accommodation

## SOME SHELTERED WORKSHOPS

Newhaven on the hill once justly no doubt called Pleasant (but now covered with steep haphazard little streets) is Searchlight a sheltered workshop for verely handicapped which has lately come of age[2] light takes its name from an old Army searchlight set up to defend us against the Zeppelins of the 1914-18 It owes its rebirth to an enterprising member of the g profession Miss Muriel Powell who is still at its head Powell had been matron at the marine branch of the g Craft School at Tidemills and had seen the cheerful d children pass out of her care to become—once the ment of their homecoming was past—a burden on their s, or inmates of chronic wards She decided if she to change that; and in 1933 with three pioneer d boys she walked into the small bungalow she had to launch her venture She found three things waiting for her a telegram of good wishes, a letter advising her not to put all her eggs into one basket and a steak and kidney pudding It was the letter that went into the basket—the waste-paper basket The other offerings, too were dealt with appropriately Since that day the bungalow has developed into a group of large and well-equipped workshops flanked by dormitories recreation rooms cottages for staff kitchens and a big dining hall which was added only last year The three pioneers were the forerunners of 44 men so severely handicapped that they are not employable in ordinary industry and hence do not qualify for the disabled persons register

In the early days Searchlight men made sweets and jam but just as a flourishing business was being built up along came the 1939-45 war to kill it stone dead with rationing Fortunately some new lines of work—wooden toy making carpentry and boot-repairing—were already being tried and presently weaving leather work and soft toy making were added The labour of running the place in war time was particularly arduous At one time Miss Powell as the only able bodied person in the place had to lift the more helpless men out of their beds into Morrison shelters when the sirens went at night and back again at the all clear With the return of peace she extended the work and had the good fortune to gather some keen and capable staff about her

There had been financial struggles from the start When her own capital ran out she was able to get local authorities to pay £1 a week maintenance grant for each man; and when this proved too little she started a farthing fund There have also been donations from friends, funds collected at a Searchlight week in Newhaven and raised by special efforts and—in recent years—donations from large voluntary funds and some commercial firms. The aim has always been to make Searchlight ultimately self supporting but the overhead costs of such a venture are high and in the meantime it needs the full support of its friends

Not long ago the Central Council for the Care of Cripples published a survey[3] of sheltered workshops and home industries run by their member organisations in south east England Besides Searchlight the workshops include Cripplecraft at Herne in Kent Hostels for Crippled and Invalid Women in south-east London Queen Elizabeth's Training College for the Disabled at Leatherhead the School of Stitchery and Lace at Bookham Grange the Woodlarks Workshop at Farnham and the Yately Textile Printers in Hampshire At Cripplecraft which is not a training centre but mainly occupational the work done includes soft-toy making basketry chair caning and woodwork; Queen Elizabeth's Workshop specialises in floral pottery and Yately in block printing of textiles by hand Bookham Grange and the Hostels for Crippled Women do fine needlework embroidery and some dressmaking and Woodlarks produces wooden toys There are home industry schemes at Brighton Hove Chichester Croydon and Kingston-on-Thames which in July 1953 (when the survey was made) were providing work for 575 men and women The work includes glove and slipper making knitting soft toy making weaving netting embroidery basket work chair caning woodwork and a number of other crafts.

Miss Norah Hill who made the survey comments that new legislation has led to an increasing awareness of the needs of the physically handicapped without so far the development of any increased provision to meet these needs There has however been a great growth of friendly feeling she finds, between Government departments local authorities and voluntary associations. The local authorities have recognised that most voluntary bodies working for the disabled "far from being inefficient, do the same job at less cost because they are able to keep down the overheads" As a result nearly all local authorities have now increased their grants to the voluntary bodies on whom they depend for services The prospects of setting up more residential sheltered workshops are poor at present but she thinks it might be possible to experiment further with non residential work centres for small groups

## University of London

The title of professor of zoology has been conferred on Mr G P Wells, SC D, in respect of his post at University College, London

On Dec 15 the degree of M D was awarded to P J Hare

## University of Glasgow

The University, with the Western Regional Hospital Board, has appointed Dr A C Forrester to the senior lectureship in anæsthetics which has been set up within the St Mungo department of surgery at Glasgow University and Glasgow Royal Infirmary The appointment carries the clinical ranking of consultant

Dr Forrester is chairman of the anæsthetic services subcommittee of the Central Consultants and Specialists Committee (Scotland) He is a consultant anæsthetist at Glasgow Royal Infirmary with which he has been associated for the past 18 years During that time he has shared in the teaching of anæsthetics to students and post graduates Dr Forrester has interested himself in the early introduction of curare into anæsthesia, and circulatory changes during anæsthesia. He has visited many other departments of anæsthesia in this country and abroad, spending some time in the U S A and Canada

Dr R C O Saunders has been appointed assistant to the senior lecturer in anæsthetics

## Royal College of Surgeons of England

Normally admission to the Hunterian festival dinner is by invitation, but this year it will be held for the first time in the new great hall of the college, and it will be possible to admit, on payment, up to 100 fellows and members Those who wish to attend the dinner, which is to be held on Feb 14, should write immediately to Mr W F Davis, deputy secretary of the college, Lincoln's Inn Fields, London W C 2, enclosing a cheque for £2 15s to cover the inclusive cost of the dinner

## International College of Surgeons

The college offers a fellowship of $3000 to a young graduate in medicine from a European or South American country

The scholarship is for travelling expenses and maintenance for twelve months Before it can be confirmed candidates must secure an appointment as a resident or fellow for one year of study and graduate work in one of the teaching centres in the United States or Canada Further particulars may be had from Dr J F Brailsford, 20, Highfield Road, Edgbaston Birmingham 15

## Royal Society of Medicine

The W J Harrison prize in laryngology has been awarded to Mr C P Wilson, and in otology to Miss M R Dix The Norman Gamble prize has been awarded to Mr J C Seymour and a Norman Gamble research grant of £100 has been made to the Institute of Laryngology and Otology

The next award of the William Gibson research scholarship for medical women (£200 p.a) will be made in July 1955 Further particulars may be had from the secretary of the society, 1 Wimpole Street, London, W 1

## Nuffield Dental Fellowships

One of the aims of these fellowships is to enable graduates in medicine and science to qualify themselves to undertake teaching and research on dental health and disease Further particulars will be found in our advertisement columns

## Royal Statistical Society

*Study Circle on Medical Statistics*—On Wednesday, Jan 12, at 6 P M at the E L M A Lighting Service Bureau, 2, Savoy London W C 2, Mr R H Thouless, SC D, will deliver on Statistics in Parapsychology

## Not Enough Nurses

Owing to shortage of nurses (says the *Richmond & T ham Times* of Dec 18) 47 beds have been closed Normanfield Mental Hospital, Teddington Because on the staff only medium grade and high grade pat be admitted in future For some time past only children have been admitted and many of these have a heavy burden on the staff The Hon John F the chairman of the North West Metropolitan Hospital Board, said that the staff situation at oth and mental deficiency hospitals was also critical Italian nurses, he added, had been recruited for two

# ANÆSTHETIST LOOKS AT A BURNT CHILD

D W SHANNON

M.B Edin F.F.A R C.S

SULTANT ANÆSTHETIST ROYAL HOSPITAL FOR SICK CHILDREN EDINBURGH

> e success of surgical treatment depends on the sum of a host ispensible contributions The best results follow only each member of a hospital team, doctors and nurses alike out their allotted task punctually and perfectly" (Learmonth

the treatment of few surgical conditions is this truth r demonstrated than in the care of a seriously burnt The prevention and the treatment of shock the ration of burnt surfaces for grafting, the outcome ese operations the relief of pain from dressing and maintenance of metabolic requirements depend not chniques of a single individual but on the coördinated s of all members of a surgical team and the ability ich member to appreciate the problems of his agues.

e purpose of this paper is to review the position of næsthetist in such a team to indicate his approach o challenge, and to suggest possible approaches to the problems as they arise

## revention and Treatment of Oligæmic Shock

matter what is the cause of oligæmic shock, its iate effect is anoxia Recent work has shown that o anoxia converts shock from a reversible process n irreversible state

oxia is also the most common cause of anæsthetic lications. Awareness of its likelihood and its nition and early treatment, are fundamental to anæsthesia It follows therefore, that the anæs st is well equipped by training and experience to o on the treatment of shock following burns

addition to correction of the ætiological factor the ment of shock should be aimed at easing the burden ie vital systems by increasing the available oxygen y by improving its transport to the tissues, and ducing the demand by the tissues

### OXYGEN TRANSPORT

er a burn fluid is lost and red cells are destroyed oportion to the extent and depth of the burn losses initiate shock and correction by replace of blood and fluid is urgent and imperative.

ere is a tendency to disparage the giving of whole and to favour the replacement of lost fluids with ia and plasma expanders alone yet in an extensive the resulting massive destruction of red cells and of hæmoglobin reduce the total oxygen capacity circulating blood to dangerous levels and present mmediate grave prognosis particularly in the The hæmoglobin lost can be made good only by fusion of whole blood The use of whole blood ver should not be confined to the extensive burn burnt patient with healing delayed beyond three has *depressed marrow function with a low red* cell count If this secondary anæmia is allowed to persist a metabolic disturbance is set up which has serious consequences to the patient It must be treated by repeated blood transfusions which aim at maintaining a hæmoglobin level of 80%

All patients with burns of more than 10% of their surface area require intravenous therapy to counter shock The volume of fluid given must be carefully calculated if it is to be adequate and overloading of the circulation is to be avoided

Empirical assessment can never be satisfactory even in expert hands Various formulæ are available That introduced by Barclay and Wallace (1954) combines safety with effectiveness and simplicity Their formula is based on the extent of the burn (fig 1) in relation to the patient's age (table I) and specifies the number of millilitres of plasma and electrolyte per 1% of body-surface burnt The calculated total is divided into three equal parts a third being given in the 8 hours immediately following the injury a third 8–24 hours after and the remaining third 24–48 hours after

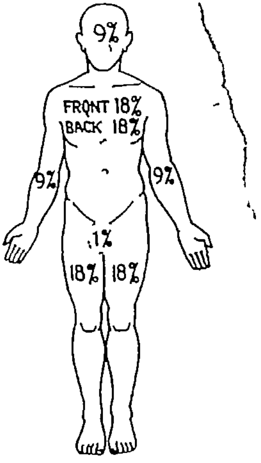

Fig 1—"Rules of nine" for estimating area of burn

Consider for instance a child aged 18 months admitted 2 hours after injury with burns involving 20% of his body-surface According to table I the requirement is 15 ml of plasma and 15 ml of saline solution for each 1% of body surface burnt Therefore 48 hours requirement for this child is 15 × 20 = 300 ml. of plasma + 300 ml of saline solution. *His requirement for the 8 hours immediately* following the burn is 100 ml + 100 ml. and this quantity must be given in the first 6 hours of treatment because he was admitted 2 hours after injury

Table I applies to burns of up to 30% of body-surface. For more extensive burns estimations from this table would lead to overloading of the circulation and volumes equivalent to 10% body weight should be given (table II)

It is important to remember that these amounts of fluid replace only the fluid lost as a result of the burn and are therefore termed replacement fluids A further adequate volume must be given to cover the normal metabolic fluid requirements of every child (table III) Such volumes are termed requirement fluids.

Replacement fluid for patients with burns of less than 10% of the body surface is given by mouth and for patients with burns of more than 10% of the body *surface intravenously*

I—BURNS OF UP TO 30% OF BODY-SURFACE : PLASMA AND ELECTROLYTE REQUIREMENTS IN FIRST FORTY EIGHT HOURS AT DIFFERENT AGES

For each kg 100 ml of fluid should be given

TABLE III—FLUID INTAKE (AS GLUCOSE DRINKS OR WATER) REQUIRED TO COVER NORMAL DAILY ME REQUIREMENTS

| — | Age (yr) | | | | | | | | | | | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | Birth–3/12 | 3/12–6/12 | 6/12–9/12 | 9/12–1 | 1–2 | 2–3 | 3–4 | 4–5 | 5–6 | 6–7 | 7–8 | 8–9 | 9–10 | 10–11 | 11–12 | 12–13 | 13–14 | 14–15 | 15–16 | 16–1 | 1 |
| Metabolic requirement (ml) | 700 | 1000 | 1150 | 1200 | 1300 | 1400 | 1400 | 1400 | 1500 | 1500 | 1500 | 1600 | 1600 | 1700 | 1700 | 1800 | 2000 | 2200 | 2400 | 2600 | 2 |

As already indicated, the restoration of circulating blood volume is of little value if its oxygen-carrying capacity (hæmoglobin) remains deficient In all patients with deep burns, and in all patients with extensive superficial burns involving more than 25% of the body-surface, where the destruction of red cells has been considerable, half the total intravenous replacement fluid should be given as whole *fresh* blood, the other half being given as equal parts of saline solution and plasma

In addition to replacement fluids, metabolic requirement fluids are given by mouth hourly unless the patient cannot retain oral fluid, as in gastric stasis and burns of the mouth, when it is also given intravenously as 5% dextrose in water

### OXYGEN SUPPLY

The urgent need for fluid replacement must not blind the clinician to the fact that anoxia, although initiated in burn cases by a decrease in the oxygen carrying capacity of the blood, is maintained and indeed exaggerated by other factors which, although not serious in themselves, may either in association with blood-loss or through their cumulative effect jeopardise the patient's recovery

Clinical anoxia cannot be classified into the compact compartments defined by Barcroft Oxygenation of the tissues depends on the integrity of several interdependent systems (fig 2), impairment of any one of which must necessarily affect all Each system must be carefully checked, if irreversible damage from anoxia is to be prevented The lungs are the reservoir from which the blood draws its oxygen In the period immediately following a burn, when blood and fluid are to be replaced, it is important—perhaps vital—that the tension and volume of oxygen in the lungs be maintained at optimal levels This depends on a clear airway and minute pulmonary ventilation

#### *Airway*

This can readily become obstructed The breathing of hot irritating fumes may cause laryngeal œdema or lead to the accumulation of desquamated cells and mucopurulent secretions in the tracheobronchial tree The patient will be cyanosed and will struggle for breath The need for clearing the airway is imperative, and treatment by tracheotomy or by bronchoscopic aspiration will, where necessary, take precedence over the replacement of fluids

Less dramatic causes of respiratory embarrassment may tend to pass unnoticed, but their very persistence in a shocked patient can delay recovery and may on occasion eventually endanger life Crusting of secretions ithin the nasal vestibules is common not only in burns olving the face but also in any dehydrated child orces mouth breathing with all its harmful effects Thick viscid postnasal secretions ooze down in laryngeal region and cause exhaustive bouts of and intensify respiratory embarrassment Some *ago a child in this unit died from asphyxiation* mucous crust blocking the laryngeal aperture cause of this sudden unexpected death was not ciated until necropsy Without doubt the nurse give the same scrupulous attention to oral and hygiene as to the care of the burnt surface

Other simple happenings, innocent in themselve often overlooked Lolling of the child's head pillow may lead to obstruction of the airway, if the tonsils and adenoids are enlarged In child, if the airway cannot be maintained by procedures, a nasopharyngeal airway lubricated analgesic (2% cinchocaine) ointment should be pass

Again, if the circulation is overloaded by replacement of fluids, a transudate fills the spaces and interferes with the diffusion of oxyge the alveolar capillary membrane This danger by the primitive and uncertain method (external on rubber tubing) by which the flow of fluids patient is apt to be encouraged It is a complicat readily occurs in young children with their small

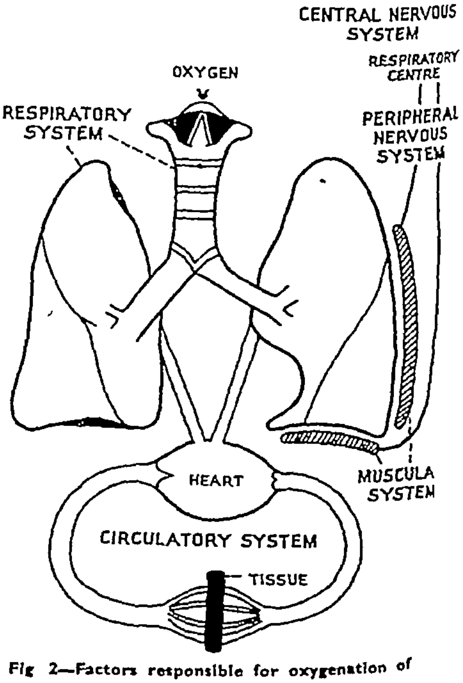

Fig 2—Factors responsible for oxygenation of

blood volume. The compromise between too little too much can be achieved only by careful and con d supervision of the drip Too often this super n is left to the nurses who lack the experience and knowledge which the safety of the child demands, furthermore it is not their responsibility

*ute Pulmonary Ventilation*

ie tension and the volume of oxygen in the lungs nd on the summation of the rate and depth of thing This depends on the integrity of the respira centre and the efficiency of the respiratory muscles r a burn there is central stimulation due to pain and *The rate of breathing is increased without a propor* ate increase in the depth This rapid shallow breath is particularly common in children with burns lving the chest and abdomen. By the relative increase ie dead air volume and the speed at which air is being n through the narrow tracheobronchial tree this type reathing is inefficient obstructive and exhausting to child The child must be given relief through the *ful administration of opiates.* Further precautions t be taken to ensure that the harmful effects are not ggerated by the application of heavy blankets or stricting bandages, and that the high Trendelenburg tion does not interfere with free intercostal and hragmatic movements

pinions differ about the value of oxygen in the tment of shock. The claims for oxygen therapy how can never be dismissed lightly since time and again he course of one s duties its undoubted value has been erienced In this unit oxygen is given routinely to dren with burns involving more than 30% of the body ace, and to any child in whom there is evidence of a ction in the pulmonary ventilation and of peripheral ulatory failure High concentrations of oxygen ease the volume and tension of oxygen in the pulmon alveoli and used as a therapeutic adjuvant, tide the nt over a period of acute anoxia while efforts are made to correct the deficiency in the circulating l volume Its value depends on a clear airway gen can neither correct nor surmount an obstructive er) and the care with which the apparatus is con d and maintained Too often one sees the oxygen der with its connections carelessly fitted fizzing uselessly or the thin rubber tubing conducting en to the patient may be kinked as it leaves the der and arches over the bed head; or a perished piece with harness inaccurately adjusted is sed and twisted and obstructs the patient s airway t of all the humidifier may be incorrectly fitted water will be siphoned into the lungs.

ygen is best given to children through an intra- catheter with several holes in its terminal inch to rse the gas and to prevent the gas from impinging antly against one spot The tube should be ated with analgesic ointment and strapped over nasal bridge and forehead leaving sufficient slack ow free movement of the child s head

ygen is delivered through a humidifier at a flow f 2–3 litres a minute and once every 12 hours the must be removed and replaced through the alternate l

y if attention is given to every detail can one be n that oxygen is being given as a therapeutic ure and not as a therapeutic gesture.

### OXYGEN DEMAND

he post war years have taught anything it is that goods are scarce one must economise in their u e simple economic law might be applied with advan o the treatment of shock In this state as has been ted, interference with the transport of oxygen ts its supply to the tissues, and the demands of the s must be reduced accordingly Consideration must be given to the handling of the patient and to the control of anxiety restlessness

TABLE IV—DOSAGE TABLE OF PREOPERATIVE AND POST-OPERATIVE DRUGS

| Age (yr) | Weight (kg) | Quinal barbitone sodium (gr) | Atropine (gr) | Diamorphine hydro-chloride (gr) |
|---|---|---|---|---|
| Birth–1 | 10 | — | 1/[illegible] | 1/[illegible] |
| 1–2 | 13 | [illegible]/4 | 1/[illegible] | 1/[illegible] |
| 2–3 | 15 | [illegible]/4 | 1/[illegible] | 1/[illegible] |
| 3–6 | 20 | 1 1/4 | 1/[illegible] | 1/[illegible] |
| 6–9 | 26 | 2 1/4 | 1/100 | 1/[illegible] |

*Handling of the Patient*

This must be reduced to a minimum only essential diagnostic and therapeutic measures being permitted. These measures must be taken with speed and precision by doctors and nurses versed in their intricacies Skill and experience are required in feeding and in setting up blood transfusion apparatus for a young child These important measures cannot be left to an inexperienced nurse or houseman who may labour for an hour or more exhausting the child and themselves before calling for assistance

*Anxiety and Restlessness*

These must be relieved Care must be taken however before administering depressant drugs that restlessness is an evidence of pain and not visible evidence of the patient s fight to relieve tissue anoxia.

Sedative drugs must be used circumspectly and their effect on the rate and depth of breathing must be carefully observed Diamorphine hydrochloride is our drug of choice for children and is given, on admission in doses based on the age (table IV) half the dose being given subcutaneously and half intravenously The dose may be repeated 4 hourly

Diamorphine hydrochloride may seem an unusual drug to select It has been used routinely in this hospital for many years as a postoperative sedative and it was a natural choice in burnt children The reputed respiratory depressant effect of diamorphine hydrochloride however with the threat of anoxia encouraged investigation of the potentialities of morphine and the barbiturates. Neither gave satisfaction. Idiosyncrasy to morphine is not uncommon in children making it unsuitable for routine use and its respiratory depressant effect appeared more pronounced than that of diamorphine hydrochloride The barbiturates (quinal barbitone sodium and phenobarbitone) as might be expected excited rather than depressed the child in pain and their repeated administration exerted a cumulative effect with prolonged and undesirable drowsiness.

On occasion a seriously burnt child has received an overdose of opiate before admission An infant aged 3 weeks admitted to this unit had been given gr 1/8 of morphine The pulmonary ventilation volume, in such a case may be reduced to a dangerous level, and it may be necessary to assist the child s breathing Oxygen is given through an *endotracheal tube, if necessary by* rhythmic manual compression of the rebreathing bag of an anæsthetic machine until the patient can actively maintain adequate ventilation

### Pre-anæsthetic Assessment

The general disturbances effecting and resulting from oligæmic shock having been corrected and brought under control consideration must next be given to the local treatment of the burn *This treatment varies from* the application of a simple dressing to extensive cleansing and grafting It therefore becomes necessary to assess the capacity of the patient to meet these operations If this assessment is to be made with any degree of accuracy the anæsthetist must be aware of the following factors

(1) The clinical state of the patient

(2) The nature of the operation, its benefits to the patient, and the metabolic and physiological disturbances associated with it

(3) The hazards of the particular anæsthetic technique required to provide satisfactory operating conditions for the surgeon

(4) The capability or possibly more important, the limitations of the surgeon and the anæsthetist

Just as the preparation of a burnt child is directed towards easing the burden on the respiratory and cardiovascular systems, so the assessment of the burnt child depends on the functional efficiency of these systems This assessment can be made only on clinical grounds Special investigations and reports by non clinical departments, although informative in a later review of the case, are necessarily delayed and often confusing, and their importance tends to be overemphasised The seriously burnt patient cannot be assessed from a single clinical examination, since the response of a shocked child, and the manner of his response, to restorative measures and replacement therapy can vary from hour to hour The clinician should rely on frequent bedside observations the colour of the skin and mucosæ, the temperature of the skin, the feel of the pulse, the capillary-filling time, the rate and rhythm of breathing, and the dryness of the tongue and lips—attempting by experience to acquire something of the clinical perception of the physicians of yesteryear

The clinician anæsthetist accompanies the surgeon on his repeated visits from the time of the child's admission to hospital, and from observations must be prepared to discuss, at any time, the advantages or dangers to the patient of whatever operation the surgeon may consider advisable

The early local treatment of burns—cleansing and the application of dressings—presents few problems to the anæsthetist The immediate threat of shock has been relieved, and these operations can be done under diamorphine hydrochloride, or the patient can be given low concentrations of cyclopropane, the gas being used as a form of controlled sedation

Later, usually between the 10th and 14th days after a burn, sloughs begin to separate, and a decision must be made about the best time for excising the eschar, whether extensive excision and grafting of the raw surfaces should be done, or whether the burnt area should be treated piecemeal

After extensive deep burns the patient's condition may begin to deteriorate between the 7th and 10th days The child becomes fevered and chesty, with a rapid pulse, or, as has happened in three cases in this unit, becomes hypopyrexial, disoriented, and later comatose It is just such patients, however, who benefit most from heroic, rather than conservative, measures The anæsthetist must be sufficiently informed on the benefits of this action to advise the surgeon on the child's ability to stand the stress of extensive surgery, and whether the anticipated blood loss can be replaced by immediate blood-transfusion or prevented by using a hypotensive drug

The custom of referring seriously ill patients to physicians for preoperative assessment is to be deplored Any member of a surgical team should be better equipped to advise than a physician, who is ill-informed on many of the essential physiopathological upsets The custom is less common than it was, but physicians, from time to time, with an enviable disregard for the hazards of anæsthesia, record as their considered opinion that a seriously burnt child will survive an operation of uncertain nature, providing a non-toxic agent, such as nitrous oxide, is used

I submit that the anæsthetist to the surgical team is [illegible]t equipped to advise on the resultant of the four [illegible]bles mentioned above He is familiar with the [illegible]ls of anæsthesia His training has taught him to appreciate the effects on the patient of blood surgical trauma associated with particular He knows, none better, the capabilities of his

### Pre-anæsthetic Medication

Atropine is given to all patients in a dose prop to the age of the patient Children tolerate large amounts of atropine and rarely show uncomfortable looking buccal and labial characteristic of the atropinised adult

In the weeks immediately following a seve repeated anæsthetics are necessary to permit and grafting operations During this period basal metabolic rate rises rapidly and may raised for several months This necessitates a intake well above normal requirements, and fr 2nd day onwards it is the custom, in this unit, for to be put on a carefully planned diet Recove anæsthesia must be rapid and uncomplicated ference with this dietetic régime is to be avoid anæsthetist should aim at having the child aw minutes of completion of the dressing or oper that food may be given within an hour or tw leaving the operating theatre For this re operative sedation is rarely used This is expressed opinion of psychiatrists, but exp given little support to their anxious forebodings or possibly because of, repeated anæsthetic the child is surprisingly coöperative, appears the frequent visits to the theatre, and, with th thetic technique detailed below, goes to sleep quietly

The occasional child who refused to become reconciled to visiting the theatre is barbitone sodium by mouth (for dosage see table drug usually puts the patient to sleep and, the rate at which it is metabolised, recovery effects is fairly rapid

Should an operation be necessary in the period diately following a burn, the child is controll diamorphine hydrochloride At this time requirements are satisfied by parenteral

The hæmoglobin level must be estimated preoper and any anæmia corrected For grafting op during which the removal of skin and the granulations will cause blood loss, it is essential blood-transfusion should be given in the preoperative period and again during the to replace any loss

### Anæsthetic Technique

Once upon a time an inspired surgeon attributed the unfortunate death of one of hi to his (the patient's) failure to " stand the an Since then this aphorism has been to the surg enlargement of the thymus has been to the an and a surgeon, before subjecting a seriously i to a lengthy and hazardous surgical operation heard to ask the anæsthetist to examine th and report on his fitness to " stand the anæsth

A review of the literature on anæsthesia, would almost certainly show that it is not the ill patient who is likely to die from an anæs the robust healthy child who has been badly Further investigation would show that the could invariably be attributed to some avoids cretion on the part of the anæsthetist The se patient appears to be unusually resistant to of anæsthesia and occasionally appears to be condition after the operation than he was before

This paradox is explained by the fact that the ill are normally anæsthetised by experienced an They are less resistant to the effects of and satisfactory operating conditions may

maintained with relatively small amounts of anæs
s In addition modern anæsthetic techniques
om being a danger to the patient embrace the
als of resuscitative therapy rest, positioning
n blood transfusions, &c
ler anæsthesia the patient is at complete rest ;
irway is carefully maintained oxygen is given in
concentration and with positive pressure if necessary
and depth of breathing are maintained at optimal
; the pulse colour, and blood pressure are con
ly observed and their significance interpreted
is given where necessary to replace loss during
sive grafting operations and the rate of the trans
is regulated to satisfy the immediate needs of
atient

s seriously burnt child to whom these restorative
res are so vitally important, shows benefit from this
ntrated attention and, providing the surgical opera
s completed without unnecessary surgical trauma
rs in better clinical condition after the operation

*hetic Agent*

's impossible to dogmatise on the best anæsthetic
for a burnt child Indeed the flood of literature
ting from different centres and extolling the
s of particular drugs for similar operations must
y confusing to the casual anæsthetist and neutral
er The truth is that the patient's safety does not
l on the pharmacology of an anæsthetic drug so
as on the skill and experience of the anæsthetist
istering it, combined with careful preparation and
ticulous application of whatever anæsthetic
que is decided on

sthetic drugs are used essentially to provide
tory operating conditions which, in similar
ons vary with individual surgeons One may be
work competently with a lightly anæsthetised
where another would require and demand
rarised pulseless, apnœic anthropomorphous
opularised by the modern anæsthetist

unately, in burns the requirements of the surgeon
All he asks is a quiet patient and access to the
areas. It is possible therefore for the anæsthetist
centrate on the demands of the child These are
ows :

rapid smooth induction free from coughing struggling
ying which exhaust the child and stimulate the
on of obstructive secretions.

high concentration of oxygen to satisfy the thera
nd increased metabolic demands of the burnt child

uiet breathing

inimal disturbance of metabolic and physiological
s The surgical team has already spent many hours
ing to correct the upset caused by the burn

apid recovery to allow full and early expansion of the
nd rapid resumption of the dietetic régime

propane is well suited to meet these demands of
l It may be given with high concentrations of
and being excreted unchanged produces minimal
f the body chemistry Its central depressant
nsures quiet breathing but most important is
a gas Absorbed and expelled through the lungs
the anæsthetist to control not only its adminis
but also its excretion This combined with the
t cyclopropane is a powerful non irritant agent
of taking a child from consciousness to respira
st in 60–75 seconds makes it the most flexible
trollable of agents, permitting rapid smooth
easy maintenance and return to consciousness
aving the operating table Feeding may be
2 3 hours later

*Administration*

ropane is administered with circle absorption
o very young (aged less than 3 years) with a
orption

TABLE V—ENDOTRACHEAL TUBES : DIMENSIONS OF MAGILL ORAL TUBES

| Dimension | Age (yr ) | | | | | | |
|---|---|---|---|---|---|---|---|
| | 3/12 | 9/12 | 1½ | 3 | 5 | 9 | 12 |
| Size no<br>Length (cm ) | 00<br>10–11 | 0<br>11–12 | 1<br>12–13 | 2<br>13–14 | 3<br>15–16 | 4<br>17–18 | 5<br>18–19 |
| Ext diam. (mm ) | 4·3 | 5·6 | 6·0 | 6·6 | 7·6 | 8·3 | 9·0 |

Rapid induction to surgical anæsthesia is achieved after five or six breaths (30–40 seconds) by giving high concentrations of cyclopropane the proportion of cyclopropane to oxygen being 3 to 1, and anæsthesia is maintained with a flow rate of cyclopropane : oxygen 1 3 (50–100 c cm of cyclopropane 300 c cm of oxygen) When the dressing is applied the cyclopropane is turned off and after one or two breaths of oxygen the mask is removed

Endotracheal intubation is used as an aid to the administration of cyclopropane in the following conditions :

(1) Burns involving the face head and neck if the surgeon is to have reasonable access to the parts

(2) Burns involving the dorsal surfaces, when positioning the child makes it difficult to maintain a clear airway

(3) Any child in whom respiratory embarrassment even though minor persists and cannot be relieved by either manipulation or the use of an oral airway

It has been suggested that the introduction of an endotracheal tube narrows the already narrow trachea of a child to a degree which itself causes respiratory embarrassment This premise stimulated the corollary that the largest possible tube should be used and has led anæsthetists to screwing into the trachea uncomfortably large lubricated tubes I believe despite assertions to the contrary that it is the maintained pressure from such tubes that initiates the formation of membranes and post anæsthetic laryngeal œdema reported recently The tube sizes detailed in table V are proportionate to the size of the child they ensure an undisturbed airway and lie comfortably within the larynx With such tubes these dangerous complications do not develop Gentle handling is necessary in introducing the tube particularly in the ill nourished child with infection of the oropharynx but provided the tube is introduced atraumatically I have not found that these factors predispose to laryngeal œdema

It is unnecessary to lubricate the tube Even although atropine has been given the slimy moistness of the child's laryngeal mucosa allows it to slip easily and atraumatically into the larynx

In children aged less than 8 years the vocal cords appear to mould themselves round the tube and an airtight fit is obtained without a pharyngeal pack.

This anæsthetic technique has been used routinely during the past eight years to anæsthetise children with burnt areas ranging from a slight extent to 60–70% of the body surface The results have been most satisfactory The only complication during administration has been an occasional bronchospasm which may be dangerous if not recognised early and rapidly relieved by the application of steady manual pressure to the rebreathing bag filled with oxygen Cardiac irregularities associated with the use of cyclopropane in adults are rarely observed and there have been no cases of postoperative atelectasis

I wish to thank Mr A B Wallace F.R.C.S.E for encouragement and help in writing this article

# THE TREATMENT OF GENITO-URINARY TUBERCULOSIS

## A REVIEW OF 240 PATIENTS

J Cosbie Ross
Ch M Lpool, F R C S
SURGEON ROYAL SOUTHERN HOSPITAL, LIVERPOOL

J G Gow
F R C S
UROLOGICAL SURGEON, WRIGHTINGTON HOSPITAL

C A St Hill
M B Brist
PATHOLOGIST, ROYAL SOUTHERN HOSPITAL, LIVERPOOL

Approximately five years ago we commenced an investigation of genito urinary tuberculosis, an investigation based on a unit of 35 beds devoted to this disease at Wrightington Hospital Previous communications (Cosbie Ross, Gow, and St Hill 1951, 1953), together with more recent papers in the *British Journal of Urology* (Ross 1953, Gow 1953) have recorded our earlier experiences The total number of patients treated now amounts to 240, and in this paper we report a new series of 85 and review the earlier groups amounting to 155 We have had the advantage of following up all our previous cases, some of whom first commenced their treatment five years ago The follow up has been carried out with great thoroughness and includes cystoscopy, intravenous and retrograde pyelography, and guineapig inoculation at first six monthly and later at yearly intervals This has naturally entailed a great and increasing volume of work, but the results have been both interesting and encouraging The careful follow up is necessary, not only because of the possibility of tuberculosis developing in another system or organ, but also because a small proportion of the urines may become positive again at the end of two or more years

It can be said at once that the prognosis has greatly improved as a direct consequence of adding chemotherapy to surgery and sanatorium treatment During the first half of this century, using surgery with or without a sanatorium regime, the mortality was approximately 50% Surgery and the sanatorium are still necessary today in the treatment of this insidious disease, but the addition of chemotherapy has reduced the mortality to 10%, and the figure is being improved year by year Our figures include all cases, no matter how advanced or extensive, since all patients with proven genito urinary tuberculosis are accepted by the unit Before chemotherapy some of these patients would have been regarded as beyond hope, and given palliative treatment only

The classification which we use is as follows

| | |
|---|---|
| *Type 1* | early minimal lesion of renal parenchyma |
| *Type 2* | unilateral renal lesion with cystitis and nephrectomy or partial nephrectomy |
| *Type 3* | bilateral renal lesion with cystitis and nephrectomy or partial nephrectomy |
| *Type 4* | cystitis and involvement of the remaining kidney after nephrectomy |
| *Type 5* | (*a*) major bilateral renal disease<br>(*b*) minor bilateral renal disease |

*This is the classification suggested by Jacobs and Borthwick* (1950) but with an additional category of "minor bilateral disease" Even in this modified form the classification is not perfect, but in practice it appears to cover most of the possibilities

We have continued to use thiosemicarbazones in addition to streptomycin, isoniazid, and *p* aminosalicylic acid (P A S ), although in other centres this policy has not received support We have been encouraged *to do so* statement by Domagk in a recent lecture that *strains* bercle bacilli which are resistant to streptomycin soniazid frequently respond to thiosemicarbazone

### Patients Treated Since July, 1952

This group consists of 85 patients (58 males females) 43 presented with renal lesions only, 42 the renal lesions were combined with pul lesions, or bone and joint lesions, or both

The chemotherapy used (Gow 1953) is briefly as

| | |
|---|---|
| Streptomycin 2 g daily, intramuscularly, in 1 dose<br>Isoniazid 250 mg daily orally, in 1 dose | administ fourteen |
| Thiosemicarbazone 100–150 mg daily orally, in divided doses<br>Calcium benzoyl P.A.S 7 g t d s | also admi for fourt |

The two combinations are alternated for a period of months

*Toxicity*

Transient toxic manifestations were caused by mycin in 22 cases, by thiosemicarbazone in 11 cases, P A S in 6 cases There were no toxic reactions to

Toxic reactions to streptomycin occurred in 25% treated, but were always mild and seldom necessita drawal of the drug The main complaints were dizz tinnitus, both of which disappeared a few weeks a course had been completed Toxic effects occurred towards the end of the course, but if they developed desensitisation was carried out by combining the strep with one of the anti histamine drugs ('Phenergan') way it was possible to give all patients a complete

Toxic symptoms due to benzoyl P.A S consisted in nau vomiting, and in 3 patients the drug had to be *Fortunately these 3 patients tolerated the original prep of P A S*

In a few cases the full dose of thiosemicarbazone h reduced to 50 or 100 mg a day because of depress anorexia.

### SURGICAL MEASURES

As we have already emphasised, surgery is as today as before the advent of chemotherapy surgical measures will remain necessary resistant strains continue, and as long as che fails to produce radiographic healing of an ulcer ous lesion In our series any improvement in the ance of the pyelogram has been the exception rat the rule

However, operative treatment should not until the patient has had an adequate period of therapy This will ensure smooth convalesc more important, *enable wounds to heal by firs* This "staging" of surgical measures carried out screen of chemotherapy has almost elimina breaking down nephrectomy wounds of previou

*Nephrectomy*

This operation was carried out in 37 cases paring this figure with the total of 85 it remembered that there was a certain number of tuberculous bacilluria (type 1) and in a few tomy had been done before the patient came care

Our indications for nephrectomy included

(*a*) A non functioning kidney

(*b*) A disintegrated kidney

(*c*) Two focal lesions not located in one pole

(*d*) An ulcerocavernous lesion in the middle a polar calyx and encroaching *on* the hilum

(*e*) "Putty" kidney There is no such autonephrectomy," and these caseous sacs inva apparent active disease when sectioned (Hanley

In all these cases the other kidney was nor only a minor lesion

We have generally found that extensive cal a kidney necessitates its removal, because from the calcified organ remains potentially

*Partial Nephrectomy*

This operation has been made possible only therapy Its advantages over total nephrecto elaboration In particular, it enables bilate measures to be undertaken We have carried hrectomy in 7 cases in the present series the operation isting in removal of the upper or lower pole or of removal of the affected part in a double kidney ral of our patients have had bilateral partial nephrec y In none have we removed the middle calyx but as been shown that this also can be done It is ourse possible to remove an ulcerative lesion and miss by millimetres an adjacent focus, but as Semb 3) has pointed out if the locally destructive lesion emoved the infiltrations usually heal with chemo apy

ie principal indication for partial nephrectomy ars to be an ulcerative lesion of a polar calyx or a lised calcified area combined with a persistently tive urine from the same ureter After partial or plete nephrectomy, our practice is to close the wound out drainage

*nsplantation of Ureter*

e have always been very reluctant to carry out this edure and it appears to be less often necessary now during the earlier years of our investigation In cases a note has been made at the initial cystoscopy owing to the state of the bladder and the severity he frequency transplantation of the ureter into the n would probably be needed later; but usually improvement in the frequency and the degree of bladder healing has made this unnecessary

his is not always so however especially where the rstitial cystitis is pronounced We have carried out nsplant on 5 occasions in the present series and is no doubt that in selected cases the operation has fully justified When the lower two thirds of the r has been extensively diseased we have not hesi to implant the upper third into the descending or the hepatic flexure in each case this has been essful Renal acidosis has been encountered on ral occasions and is nearly always due to neglect on art of an uncooperative patient When the simple involving the constant use of an alkaline mixture salt free diet are combined with periodic analysis blood chemistry little trouble has been encoun When there is a progressive hydronephrosis from ure of the lower end of the ureter we prefer to nt the dilated lower end of the ureter in the fundus bladder provided the condition of the bladder is actory

have carried out nipple ureterostomy (Band 1950) ne of these intractable cases Theoretically nipple ostomy is attractive because it removes the twin rs of ascending infection and renal acidosis more an efficient apparatus for collecting the urine can e provided But while acknowledging its possible in other conditions (e.g., cauda equina lesions) we recommend ureterostomy in renal tuberculosis ureter is diseased as is likely in patients in whom diversion is indicated ulceration and fistula ion occur at the base of the skin nipple We have re abandoned this procedure

*ymectomy*

rculous epididymitis is common and nearly a f our patients had genital lesions We have been sed by the large numbers of patients with a tuber epididymitis combined with type 1 renal lesion idymectomy is apparently not now required as it was two or three years ago It was performed 7 of our 85 patients The operation is however ressary when caseation and abscess formation are and especially if the vas is involved If the mis feels hard or fibrotic it may be safely left on-operative treatment will probably be effective ectomy has not been included in our list of ive procedures because we feel very strongly that utilating operation should not be performed unless the circumstances are quite exceptional It is not an urgent matter to remove the epididymis and especially if there is a large confluent inflammatory mass, there is every advantage in postponing the operation for three or four months while the patient is in the sanatorium receiving a course of chemotherapy If patience is exercised, sufficient improvement will be achieved to enable the operator to find a plane of cleavage between the body of the testis and the epididymis The technique (Ross 1948) involves the extrusion of the testis through a scrotal incision the careful preservation of the blood supply of the body and the bringing out of the stump of the vas through a small stab incision over the external ring

RESULTS

These have been assessed under the following headings (1) sterilisation of the urine (2) clinical improvement and (3) cystoscopic improvement

*Urine*

All were guineapig positive before treatment was begun and of the 85 patients no fewer than 80 achieved a stable negative 5 were unstable but none was persistently positive (table I) 5 had reverted to positive at the end of six months (the longest follow up possible in this group up to the present time) The tubercle bacilli isolated from all positive cultures or guineapig inoculations were tested for sensitivity to streptomycin and isoniazid no strains resistant to streptomycin or isoniazid were isolated

TABLE I—FOLLOW UP OF 85 CASES

|  |  | Urine |  |  |  |
|---|---|---|---|---|---|
| Type | No. of cases | Positive after two months | Positive after four months | Positive after six months | Reverted to positive after six months |
| 1 | 28 | 0 | 1 | 1 | 1 |
| 2 | 34 | 1 | 4 | 1 |  |
| 3 and 4 | 14 | 3 | 0 | [illegible] | [illegible] |
| 5 | 9 | 2 | 1 | 0 | 2 |

1 patient died from advanced pulmonary disease about six months after leaving hospital

For some time we have considered the period of six months chemotherapy to be insufficient —a view which is held by various Scandinavian authorities (Ljunggren 1953) Accordingly we now give in addition a modified course lasting three to six months, after the patient leaves hospital This post sanatorium course is given by the patient's own doctor and consists of

Streptomycin 2 g intramuscularly } twice a week together with
Isoniazid 200 mg orally }
Calcium benzoyl P.A.S. 3 g orally three times a day

*Clinical Improvement*

We have attempted to judge the clinical improvement by the degree of frequency of micturition and nocturia and by the gain in weight Of the 61 patients who originally complained of frequency and nocturia 57 were considerably improved but 4 ultimately required ureterocolic transplant for intractable bladder symptoms 72 patients put on weight the average gain being approximately 1 stone

*Cystoscopic Improvement*

Of the 85 patients 60 had tuberculous cystitis or tuberculous granulations and many had both Of these 50 showed improvement and in 30 the bladder returned to a normal appearance Of 34 with a reduced bladder capacity a considerable increase was recorded in 32.

As in the past we have not seen any improvement in the radiological appearance in the present series

**Follow up of Patients Treated Prior to July, 1952**

93% of the patients treated since 1949 have been followed up (table II) Our aim is to keep as many

TABLE II—RESULTS OF FOLLOW-UP

| Year | No of patients | Died | Given further course of treatment | Positive at end of treatment | Reverted | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | After 1 year | After 2 years | After 3 years | After 4 years | |
| 1949–50 | 51 | 8 following transplant<br>1 advanced pulmonary disease<br>1 severe bilateral renal disease | 3 | 9 | 2 | 2 | 3 | 4 | |
| 1950–51 | 17 | 2 following transplant<br>2 meningitis<br>1 advanced pulmonary disease | 1 | 12 | 5 | 1 | 2 | 1 | |

| 1952–53 | 30 | 2 severe bilateral renal disease | 2 | 1 | 6 | 2 | 0 | 0 | |
| Total | 155 | 18 (*11 6%*) | 8 (*5 1%*) | 23 (*14 9%*) | 15 (*9 7%*) | 7 (*4 5%*) | 6 (*3 9%*) | 5 (*3 2%*) | |

patients as possible under constant review for ten years from the start of treatment

ANALYSIS OF URINARY INVESTIGATION SINCE 1949

During the present period further efforts have been made to improve our methods for isolating tubercle bacilli from urine In previous investigations we had found that twenty-four-hour specimens did not yield a higher proportion of positive results than early morning specimens In an attempt to improve the twenty four-hour specimen results, the volume of urine from which a sediment was obtained after forty eight hours' standing was increased, firstly to 250 ml and secondly to 750 ml Table III shows that increasing the volume of twenty four-hour urine specimens did not increase the number of positive results We believe that several factors account for this

In the first place, twenty four hour specimens are collected at intervals in the ward and are open to many contaminants, including moulds and bacteria relatively resistant to the action of sodium hydroxide Many specimens have accordingly to be treated twice with sodium hydroxide, which doubles the risk that the sodium hydroxide will kill the tubercle bacilli as well Secondly, most twenty four hour specimens develop large amounts of phosphatic and other deposits, which impede the action of the sodium hydroxide, and lead to the production of bulky and unwieldy material for final inoculation We have consequently abandoned using twenty four hour specimens, believing that the results from early morning specimens are equally good The results of the first 200 early morning specimens have been compared with those of the preceding twenty four hour specimens (table IV) There was no significant difference between the early morning and twenty four hour specimen results, and the results from artificial culture were as good as from guineapig inoculation It was noteworthy that the number of positive results obtained when the two methods were combined was consistently higher than when either method was used alone

TABLE III—EFFECT OF INCREASING VOLUME OF URINE CENTRIFUGED

| Vol centrifuged | No tested by artificial culture | No positive | No tested by guineapig inoculation | No positive |
|---|---|---|---|---|
| 100 ml | 441 | 20 (*5%*) | 284 | 68 (*24%*) |
| 250 ml | 230 | 16 (*7%*) | 230 | 60 (*26%*) |
| 750 ml | 119 | 28 (*7%*) | 419 | 50 (*12%*) |

Sodium hydroxide, which we used to destroy contaminating organisms in our specimens, is reputed to kill tubercle bacilli as well as contaminants We therefore incorporated chloramphenicol in the Löwenstein-Jensen medium, in the hope that it would suppress the growth of contaminants and do away with the need for using sodium hydroxide All specimens from which no growth was obtained on a preliminary overnight culture on blood agar (containing 10 µg of chloramphenicol per gramme of medium) were inoculated on to Löwenstein media without any further treatment We found ause of the lability of chloramphenicol 100 µg had lded to each gramme of Löwenstein Jensen medium to suppress contaminants for six weeks At this growth of the tubercle bacilli themselves was inhibited

We therefore reduced the time that the sodium hyd (3%) remained in contact with the urinary deposits twenty minutes to five minutes We found that five m was long enough to decontaminate practically all our s mens, but that the proportion of positive tubercle b cultures was not increased by the shorter time From follows either that 3% sodium hydroxide is not let tubercle bacilli immersed in it for twenty minutes, o lethal effect is not lessened by shortening the time o

TABLE IV—COMPARISON OF CULTURE METHODS

| Specimen | No of specimens | No positive by artificial culture | No positive by guineapig inoculation | Com no po |
|---|---|---|---|---|
| Early morning | 202 | 19 (*9 5%*) | 19 (*9 5%*) | 28 (*1 |
| 24 hour | 419 | 28 (*7%*) | 50 (*12%*) | 54 |

The technique we now employ is

The early morning specimen is collected and diately to the laboratory, where the whole of it is for half an hour at 2000 r p m , the deposit is tre 3% sodium hydroxide at 37°C for five minutes, ne centrifuged for twenty minutes and the resultant inoculated on to two Löwenstein Jensen plates an guineapig

TREND OF RESULTS

The over-all figures for the proportion of isolations of tubercle bacilli from urinary s received during the last three years are given in In the early stages the proportion of positive res high this was to be expected, for many from untreated cases As the trial proceeded, the tion of treated to untreated cases rose steadily, was reflected in the steady fall in the number of guineapig results The proportion of positive obtained by artificial cultures, on the other hand diminish consequently, while guineapig inocu first gave better results than artificial culture, both methods gave very similar results The ex probably lies in the improvements which we mad technique over the past three years the tu in our final deposits are now in sufficient n allow growth on artificial culture media as guineapigs Each method will of course which explains why the combined results are b those of either method taken individually (table

TABLE V—RESULTS FOR LAST THREE YEARS

| Specimen | No tested by artificial culture | No positive | No tested by guineapig inoculation | N |
|---|---|---|---|---|
| Early morning | 765 | 82 (*10 5%*) | 559 | 49 |
| 24 hour | 1297 | 78 (*6%*) | 962 | 184 |

### Discussion

e have been concerned by the emergence of resistant ns of organisms in a small number of patients ed in earlier groups In some of these the resistant nisms have been found when a previous course of ment often inadequate, has been given elsewhere void this difficulty we have for some years given the drugs in pairs alternately for two weeks at a time bove) By this means not only are resistant strains less likely to occur but toxicity is reduced to a num. Further, it is now well established that zid and streptomycin given together are much effective than either given alone (Mackaness 1953) e is no place in the treatment of genito urinary culosis for prolonged administration of a single

cently there was reported the result of a clinical trial e United States of America of an isoniazid derivative 213) Although this new preparation is weight for it slightly less active than isoniazid it appears to be t one-tenth as toxic (Bavin et al. 1952 Katz et al For patients who fail to respond to streptomycin and azid or who have become resistant to one or both s we have recently instituted an alternative course sting of 1 5 to 2 0 g of H P 213 combined with vio n 2 g a day The combination is given for periods ortnight, alternating with fortnightly courses of thio carbazone and calcium benzoyl P.A.S Viomycin has given with caution because of its toxicity, but using method of intermittent dosage we have not so far any trouble A careful watch for the appearance of nin is especially important

have been encouraged to learn that other workers lvising long intermittent courses of treatment for ulosis of other organs (Joiner et al 1954) We have tently advocated this policy for a number of years

*cted Bladder*

ere tuberculous cystitis may often heal completely ay leave the patient with troublesome residual oms of frequency and nocturia due to a contracted r Superficial cystitis heals well, but interstitial s may leave a diminished capacity Thornley suggested that cortisone might be useful in these and we have therefore treated a small series with f cortisone spread over a period of four weeks. was administered daily for two weeks, followed by daily till the whole gramme had been given Only s in whom the disease had been inactive for some ave been considered suitable for this form of ent So far results are not encouraging

*sive Hydronephrosis*

ur experience patients with progressive hydro sis usually do not improve, and we have not had success with such simple measures as ureteric on (Lane 1954) It is often difficult to pass a catheter in these cases, and subsequently, at on we have found the lower third of the ureter lod in a solid mass of fibrous tissue When only er third of the ureter is involved it may be possible ant the upper end into the bladder fundus If r there is tuberculous cystitis and if much of ter is involved a ureterocolic transplant is best out

*cy and Genito urinary Tuberculosis*

present policy is to allow the pregnancy to con rovided the renal disease is not widespread and l also that the lungs are not much involved If on is of minor degree a normal confinement is ed, the chemotherapy dosage being reduced by ing the last few months of pregnancy Frequent tions of the urine for albumin are necessary s advisable to carry out intravenous pyelography once or twice to make sure that the minor renal lesion shows no signs of spread. Should spread occur it is advisable to terminate the pregnancy forthwith

### Summary

We have continued our investigation of genito urinary tuberculosis Another 85 cases are discussed.

The 155 patients of our earlier series, some of whom began treatment in 1949 have been regularly followed up The results are reviewed

It was found that these patients had to be followed up indefinitely since the urine reverted to positive within twelve months in 9 7% and within two years in 14 2%

Further experience confirmed our belief that anti tuberculous drugs should always be given in combination and that the intermittent method of therapy offers great advantages

Further experience also convinced us that the course of treatment should be continued up to a year, and even longer

A new course was used in patients with strains of organisms resistant to the usual drugs

By combining surgery and a sanatorium régime with modern chemotherapy the prognosis has been greatly improved

We should like to thank Mr J Dobson consultant surgeon superintendent Wrightington Hospital for his help and cooperation Prof D T Robinson who was responsible for the guineapig inoculation tests and Smith & Nephew Research Ltd. for technical assistance and supplies of isoniazid thiosemicarbazone benzoyl P.A.S and H.P 213 We are grateful also to Mrs C. Wilding who carried out all the technical laboratory work, and to the medical research committee of the board of governors, Liverpool United Hospital who have provided one of us (J G G) with a grant to assist this investigation

No one can prevent young people asking questions—the same awkward questions—of the generation that precedes it. My greatest hope I think, lies in this restless searching for satisfactory answers that goes on in young people's minds before they lapse into the acceptance that tends to come with age for by it truth can be reborn. Nothing can still this unquiet pulse Between the ages of perhaps fifteen and twenty five we question and establish our fundamental beliefs In the future I think we must somehow seize the exciting opportunity this gives In the lifetime of each person this chance comes only once Is it not possible to encourage in our youth a love of hardship adventure and effort to give greater training in service and citizenship so that later a spontaneous awareness arises of problems at home and abroad of religion and of politics ? This enquiry may lead to one religion, to another religion or even to no religion It may lead to one political party another political party or to no political party But at any rate I believe it will strengthen in all of us a conviction of the value of individual freedom and unless we know its value we cannot defend it —Dr ROGER BANNISTER, *The Listener* 1954 52, 1141

# CHRONIC BRONCHITIS

## AN ATTEMPT TO CONTROL CHRONIC INFECTION WITH HÆMOPHILUS INFLUENZÆ BY AEROSOL THERAPY

Kay Knox
M B Dubl, D C P
REGISTRAR IN BACTERIOLOGY

P C Elmes
M D West Reserve, B M Oxfd, M.R C P
M.R C RESEARCH FELLOW

C M Fletcher
O B E, M A, M D Camb, F R C P
SENIOR LECTURER IN MEDICINE

POSTGRADUATE MEDICAL SCHOOL OF LONDON,
HAMMERSMITH HOSPITAL

In chronic bronchitis there is colonisation of the bronchial tree by nasopharyngeal bacteria (Stuart-Harris et al 1953), which may be classified into two groups (May 1953)

(1) "Pathogens" pneumococcus, *Hæmophilus influenzæ*, *Staphylococcus aureus*, group A hæmolytic streptococci, and Friedländer's bacillus

(2) "Non pathogens" *Streptococcus viridans*, non hæmolytic streptococci, diphtheroids, *Neisseria catarrhalis*, and *Staph albus*

During the summer months and between exacerbations in the winter one or more of the "non-pathogenic" bacteria usually predominate in mucoid sputum, although pathogens may be present in small numbers During this phase antibacterial drugs temporarily reduce the number of bacteria and of inflammatory cells (Elmes et al. 1953) but have very little clinical effect During an exacerbation there is proliferation of one of the "pathogens," usually either a pneumococcus or *H influenzæ*, and the sputum becomes purulent, but we have observed that this may follow the onset of clinical symptoms in some instances, hence the bacterial infection may be the consequence rather than the cause Antibacterial drugs given during an exacerbation suppress the "pathogens," the sputum becomes less purulent, and there is usually clinical improvement

Reid's (1954) pathological studies suggest that during these exacerbations, while the bronchioles are temporarily occluded, permanent damage may be caused to the lungs by extension of inflammation to the lobules Presumably the bacteria concerned belong to May's "pathogen" group, therefore their suppression during an exacerbation should both reduce its length and severity and delay the gradual deterioration of lung function which is characteristic of this disease Prophylactic treatment to prevent proliferation of these bacteria should be directed particularly against *H influenzæ*, since the drugs to which it is sensitive will also suppress pneumococcal infections

Systemic penicillin, in doses likely to be tolerated over long periods, encourages the proliferation of *H influenzæ* Of the "wide spectrum" antibiotics chloramphenicol is the most effective against *H influenzæ*, but its effect is only temporary, and long term administration is precluded by its toxicity Combinations of streptomycin and penicillin have been advocated by Mulder et al (1952), but constant systemic streptomycin is impracticable for the treatment of large numbers of bronchitics apart from the danger of damage to the labyrinths from the doses needed We therefore tried local therapy with streptomycin and penicillin in patients with chronic *H influenzæ* infections to see whether such therapy could be applied effectively for long periods without serious complications such as sensitivity to the drugs and a serious proliferation of insensitive organisms Although theoretically promising, this method did not prove
le in a pilot trial made on a small group of inpatients
utpatients, which is the subject of our present brief

## Material

Details of the cases are given in table I The inpatients (cases 1–3) had been admitted with exacerbations of their chronic bronchitis and were to have a predominant growth of *H influen-* sputum The six outpatients were not acutely ill treatment was started but were less well than th been in the summer All were known to have predominant infection with *H influenzæ* for at month, some for more than a year, and they ha under observation during the preceding winter had received chemotherapy within a month of th of the trial

## Methods

*Clinical Assessment* —With the exception of the outpatients attended weekly, and their was assessed by standard questions and clinical tion Case 4 was seen less frequently but sent specimens of sputum and progress reports

*Treatment* —The dose of penicillin G and sulphate was dissolved in 1 5 ml of 0 5% sulphate This was dispensed in rubber sealed containing a week's supply and retained its at room-temperature over this period The measured out the dose with a 2 ml syringe and

TABLE I—DETAILS OF CASES

| Case no | Age (yr) | Sex | Grade of dyspnœa at best (Fletcher 1959) |
|---|---|---|---|
| *Inpatients* | | | |
| 1 | 74 | M | 4 |
| 2 | 67 | F | 4 |
| 3 | 63 | M | 2 |

electrically driven 'Deedon' plastic inhaler with mask They were instructed to gargle and to faces and hands after each treatment to dimi risk of skin sensitisation The inhalation from fifteen to twenty minutes All the outpatie using a hand spray to administer compound and atropine spray (*N.F*), when necessary, to bronchospasm

*Bacteriological* —The techniques of mechanical genisation, culture, and viable counting were described by Elmes et al (1953) Gutters for mycin sensitivity testing contained 200 µg streptomycin, and the control organism was *aureus* To facilitate the identification of *H* 0 2 unit of penicillin per ml was incorporate chocolate agar medium The streptomycin homogenised sputum was estimated by the me by Mitchison and Spicer (1949) for serum fluids The lowest level of streptomycin which detected by this method is 1 µg per ml The Abraham et al. (1941) was used for the esti penicillin, except that agar seeded with the staphylococcus before pouring was used in surface inoculated medium

*Microscopical* —Sputum smears were analysed by the method described by Elmes et al

## Results

The inpatients were used to determine what penicillin and streptomycin should be given method

*Inpatients*

**Case 1** was given penicillin 200,000 units and str 0 2 g twice daily, and specimens of sputum taken were cultured and tested for the presence of pen

Despite courses of chemotherapy

tomycin The sputum contained an effective level of cillin (8 units per ml ) twelve hours after the start of tment but streptomycin was never detected During the three days *H influenzæ* was found occasionally in the um; hence antibiotic cover was not being provided ughout the twenty four hours of each day but after the th day of treatment all the specimens collected before the *ning treatment contained no H influenzæ By the end of* first day the sputum had become mucoid and its volume progressively until after the third day it was only possible btain a small morning specimen Treatment was continued ten days. Five days later *H influenzæ* reappeared in the um in large numbers, although the character of the um hardly changed and the patient s clinical condition nued to improve until the time of discharge a few days

Seen as an outpatient a month later his condition had iorated and he was again coughing up large volumes of ent sputum yielding a profuse growth of *H influenzæ*

se 2 was too ill to coöperate well in taking the inhalations reptomycin 0 5 g and penicillin 200 000 units twice daily fection was only partly controlled When the dosage ncreased the antibiotics tended to crystallise out in haler and the treatment became even less effective. nfection responded well to parenteral penicillin and tomycin

se 3 —Despite a predominant growth of *H influenzæ* atient was producing a large volume of mucoid sputum treatment was started with penicillin 500 000 units and omycin 1 g twice daily Initially difficulty was caused ugs crystallising out in the vehicle but this was pro l by adding distilled water After this had been done *luenzæ* disappeared from the sputum which decreased ume and became less cellular The treatment was ined for twelve days, during the last four of which *monas pyocyanea* appeared in the sputum in moderate rs without any clinical or microscopic change Within hours of the last treatment the patient developed n and increasing dyspnœa, but it was not until three days hat his sputum became purulent and *H influenzæ* ared. He was by then desperately ill was treated with nphenicol cortisone and Alevaire and recovered. phils did not appear in his sputum until he had been isone for three days; therefore it is unlikely that the nation was due to sensitivity to the aerosol There change in this patient s agglutination titre to the n pathogenic respiratory viruses at this time (The test ide by the Virus Reference Laboratory Colindale )

*ients*

vas decided to give the outpatients penicillin ) units and streptomycin 0 4 g in 1 5 ml of vehicle laily

results are summarised in table II which shows *influenzæ* was satisfactorily eliminated from the n only in case 8 who was also the only patient in exacerbation of his bronchitis during treatment utum always contained large numbers of poly but was not grossly purulent His relapse utely after the cessation of treatment was associated with the reappearance of large numbers of *H influenzæ* in his sputum indicating that this infection had been suppressed rather than eradicated He responded to a further course of penicillin and streptomycin inhalations but relapsed again when this was stopped

An exacerbation was defined as a sudden clinical deterioration with pyrexia and breathlessness causing the patient to stay in bed for two or more days Such exacerbations developed during treatment in all the other outpatients, but only one (case 9 first exacerbation) was associated with a change in flora This took place when *H influenzæ* could not be cultured from the patient s sputum and when his inhaler was out of order it was associated with the proliferation of a pneumococcus and responded to further inhalations and parenteral penicillin

All the other exacerbations took place while *H influenzæ* was present in the sputum although not necessarily in large numbers Since *H influenzæ* did not proliferate significantly with the exacerbations it seems unlikely to have been the cause

### *Bacteriology*

Total viable counts on the specimens from the inpatients in whom the treatment was effective showed a reduction from $10^6$ to $10^4$ bacteria per ml in case 1 and to zero in case 3 This reduction lasted about three days and then the total count increased rapidly to the pre-treatment level even though the pathogen was still absent. Viable counts on the outpatients done weekly for the first two or three weeks showed no significant change and were not continued There was no significant change in the flora other than those mentioned above

### *Microscopy*

As in our previous study the microscopical findings in the sputum showed a good correlation with the clinical state of the patient During exacerbations the polymorphs and deoxyribonucleoprotein fibres increased at the expense of the mucoprotein but when the sputum was mucoid between exacerbations although it might contain no deoxyribonucleoprotein fibres the neutrophil polymorph was still the most numerous cell Eosinophils were present from time to time in the sputum of all the patients but seldom in greater proportion than 5% of the total cells present; their presence was not correlated with any clinical symptom or sign

### *Side-effects*

No evidence of either cutaneous or bronchial allergy developed in any of the patients although there were occasional breaks in therapy of up to a week due to mechanical failures No disturbance of gastro-intestinal function nor any other side-effect was noted The patients found the inhalations tasteless.

### Conclusions

Our conclusion is that our method of administering penicillin and streptomycin as an aerosol cannot be relied on to control bronchial infection by *H influenzæ* Furthermore, even the one case in which the infection was controlled for as long as six months relapsed immediately after the treatment was stopped The reason for the failure of the method in five out of six patients is not clear, because the persistant organisms retained their original sensitivity to penicillin and streptomycin Perhaps the uneven distribution of an inhaled aerosol in emphysematous patients permits foci of infection to persist in parts of the lung to which the aerosol does not penetrate

Our observations support the view that *H influenzæ* is of importance in severe chronic bronchitis We have already shown (Elmes et al 1953) that patients infected by this organism appear more susceptible to the effects of fog than those without it, and in our present small series only the patient whose infection was controlled escaped an acute exacerbation while the treatment continued The exact rôle of *H influenzæ* in chronic bronchitis remains obscure Although exacerbations occur more frequently when it is present, they are not always associated with proliferation of *H influenzæ*, nor does a proliferation of this organism necessarily cause a clinical exacerbation

### Summary

An aerosol of penicillin and streptomycin was used in an attempt to suppress *H influenzæ* infections in nine patients with severe chronic bronchitis

It was successful in three of them with clinical benefit

In the others *H influenzæ* persisted in the sputum, and they had winter exacerbation of their bronchitis

The bacteriological and clinical findings are described

We wish to thank Dr S Sherlock and Dr R I S Bayliss for permission to treat their inpatients, members of the staff of the departments of medicine and bacteriology who made some of the observations when we could not do so, Miss M Burton for preparing the solutions for inhalation, and Moore Medicinal Products Ltd for the loan of the electrically driven Deedon inhalers

# HEART-FAILURE FROM RETENTION OF SALT AND WATER CAUSED BY TREATMENT WITH PENTAPYRROLIDINIUM BITARTRATE

VAGN RONNOV-JESSEN*
M.D Copenhagen
ASSISTANT PHYSICIAN, FREDERIKSBORG COUNTY CENTRAL HOSPITAL, HILLERØD, DENMARK

DURING the past fifteen months we have been treating with pentapyrrolidinium bitartrate (' Ansolysen '), usually by mouth, about 100 patients with severe hypertension The results much resemble those obtained by Smirk (1953)

The patients included several who had symptoms of heart-failure before treatment, and usually these symp[illegible] soon disappeared It was therefore especially [illegible]ble that during treatment 2 patients with relative failure developed symptoms of absolute failure, with œdema and dyspnœa at rest Moyer and Mills ( have shown that after the administration of a singl of hexamethonium the renal excretion of wate sodium chloride decreases The same applies to pyrrolidinium I therefore tried to find out i symptoms of heart-failure were due to this retenti salt and water

### Investigation

5 of our hypertensives were given a diet containing about 8 g of sodium chloride They received this diet for eight days before treatment, and for the first two or three treatment During this time the daily urinary ex of sodium, potassium, and chloride was measured. P pyrrolidinium bitartrate was injected hypoder thrice daily at 7 A M, 2 P M, and 9 P M The init was usually 1 25–2 50 mg, and the dosage was gradually as the patients became habituated The b pressure in the erect and recumbent postures measured thrice daily at 8 30 A M, 12 30 P.M, 6 P M

The urinary excretion of sodium chloride in all the patients at the beginning of the tr but the degree of retention varied much from one p to another 1 patient developed symptoms resembling those of cardiac asthma

**Case 1** —A housewife, aged 62, had had for many years During the past year she had had dyspnœa on slight exertion, such as ordinary walking had never had dyspnœa at rest or cardiac pain She was dizzy, and her memory was poor

*On examination* she was somewhat overweight, with of the lips and slight dyspnœa at rest On auscultation lungs there was slight basal crepitation, respirat vesicular The heart was enlarged, its action was and a systolic murmur was heard over the aorta The was obese The liver was not palpable, and there ascites There was slight œdema of the ankles Blood on admission was 270/145 mm. Hg

*Laboratory Investigations* —Hæmoglobin 93–91% cyte sedimentation rate 20 mm in 1st hr, blood urea per 100 ml The urine contained no blood, protein, sp gr 1 007–1 018 Electrocardiography showed T waves in the first and second leads, and left axis Radiography showed considerable enlargement of especially to the left There was no pulmonary

*Treatment and Progress* —During the whole of her hospital the patient was given a diet containing of sodium chloride daily Since, after a week in her blood-pressure was still about 225/140 mm. Hg the erect and the recumbent postures, hypodermic ad tion of pentapyrrolidinium bitartrate was institute initial dose was 1 25 mg t i d, increasing to 6 25 mg she developed tolerance During the first few days, the felt well, and her blood pressure was about 170/10 in the erect posture However, after twelve days' tr she began to feel tired again, and on the fourteenth treatment she woke in the morning with dyspnœ subsided spontaneously On the fifteenth day she c lie down, owing to pronounced dyspnœa, which present in the sitting posture Moist râles were hear on auscultation of the lungs, and considerable œde ankles had developed Her blood pressure was factory, about 145/100 mm Hg, but, since her dition had apparently been caused by the treatment discontinued The dyspnœa became worse in the co day, so in the evening we started treatment with diuretics A profuse diuresis occurred during the next morning the patient felt much better, she then slight dyspnœa at rest Treatment with was resumed, this time by mouth, and a mercuria was given once a week During the past month has felt well, her blood pressure is about 170/105 in the erect posture, and 185/115 mm. Hg in the r posture Fig 1 shows the patient's weight, Hb and urinary excretion of sodium and chloride shows that considerable hydræmia developed dur ment The excretion of sodium chloride before treatment shows that the patient retained about

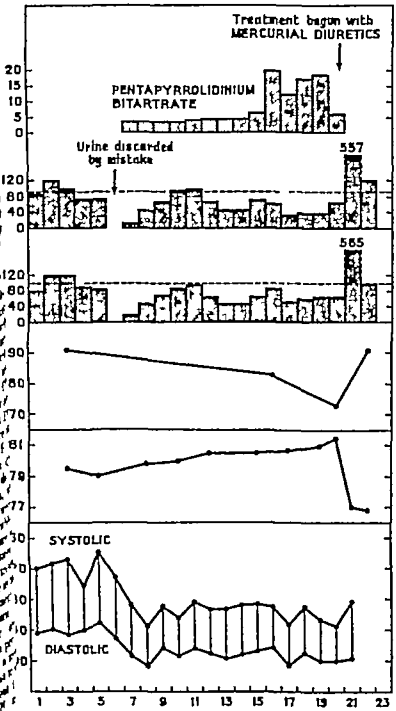
---

Aided by a grant from P Carl Petersen's Foundation substance Her weight increased by 2 5 kg and, since received a low calorie diet at the same time it can be n for granted that at least 2 5 kg of water was retained the other hand the urinary excretion of potassium was slightly influenced except that it was somewhat decreased ng the first two days treatment.

efore treatment this patient was on the border of plute heart-failure but it was undoubtedly the ntion of salt and water caused by pentapyrrolidinium caused her cardiac asthma

he 2 above-mentioned cases with similar symptoms ch were responsible for this investigation into the ary excretion of salt and water during treatment with apyrrolidinium were as follows

ase 2.—A housewife aged 61 with severe hypertension and ertensive heart-disease Six days after admission her d pressure was still about 230/140 mm. Hg oral treat t with pentapyrrolidinium bitartrate 20 mg four times y was therefore instituted After twenty three days ment she was discharged with instructions to take ng four times a day Except for some fatigue she felt then. Since the beginning of the treatment she had ased her weight by 6 kg A fortnight after discharge was readmitted owing to great fatigue dyspnœa on tion and increasing abdominal circumference. Examina now showed that she had congestion of the lungs and iderable ascites; since the start of treatment five weeks er her weight had increased by 11 0 kg and her Hb decreased from 93 to 78% (hydræmia) We continued treatment but administered mercurial diuretics also ing this regimen the patient lost 15 4 kg and her Hb



Hæmoglobin body-weight, blood-pressure and urinary excretion of chloride and of sodium in case 1

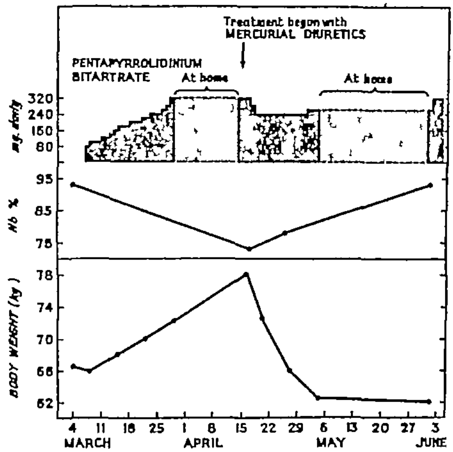


Fig 2—Hæmoglobin and body-weight in case 2. Note hydræmia accompanying increase of weight.

increased to its previous values. Since then she has felt well during three months continued treatment with pentapyrrolidinium combined with injections of mercurial diuretics once or twice weekly Her blood pressure is about 180 120 mm. Hg in the erect posture and 210/120 mm. Hg in the recumbent posture Fig 2 shows her weight and Hb values during treatment

**Case 3**—A hospital nurse aged 52 with considerable hypertension and mitral stenosis. Oral treatment with pentapyrrolidinium exerted a beneficial effect on her headache and dyspnœa on exertion, but the effect on her blood pressure was somewhat fluctuating and several times she developed symptoms of overdosage—dizziness and vomiting At the same time she had slight dyspnœa at rest, tickling cough, and signs of pulmonary congestion on auscultation These symptoms always subsided when the dose of pentapyrrolidinium was temporarily reduced

Even though the salt and water excretion before and during treatment was not investigated in these two cases there can hardly be any doubt that the symptoms in both cases were due to salt and water retention caused by the treatment with pentapyrrolidinium

### Discussion

During treatment of hypertension with pentapyrrolidinium some water and some salt are retained in the organism. The cause of this is not yet known Pentapyrrolidinium may possibly influence the kidneys directly but it is also possible that the reduction in the blood pressure prevents an affected kidney from excreting salt and water The latter probably plays at least some part for in the case of intravenous administration of veratrum preparations a pronounced antidiuretic effect is also observed (Freis et al 1949 Meilman 1953) in spite of the fact that the reduction of blood pressure by the veratrum preparations is chiefly of central origin whereas that produced by the methonium preparations is due to ganglionic block

Similar cases during hexamethonium treatment have not been reported hitherto but Persson (1951) has observed an increase of the patient s weight in several cases during hexamethonium treatment and I have observed the same Owing to the rather short duration of the effect of hexamethonium it is difficult with this form of treatment to keep the blood pressure effectively lowered throughout the twenty four hours and this may be the reason why the retention of salt and water is not enough to give rise to alarming symptoms

In our department we have seen severe symptoms in 3 of about 100 hypertensives treated with pentapyrrolidinium, *and in several others we have seen a* transient tendency to œdema at the beginning of the treatment This is of no slight practical importance, this retention of salt and water is not harmless, since, as shown by the cases cited here, it may give rise to alarming symptoms In such cases unawareness that pentapyrrolidinium causes retention of water and salt may lead to continued treatment, which may be useless or even harmful, but it should be possible to avoid these symptoms of circulatory disturbances by relatively simple measures The following rules should be observed

(1) During the early part of treatment every hypertensive treated with pentapyrrolidinium should be weighed twice a week.

(2) If the patient's weight increases considerably during treatment, he should be closely observed, and, if symptoms of decompensation develop, mercurial diuretics should be administered, or else the dose of pentapyrrolidinium should be reduced

### Conclusion

The treatment of hypertension with pentapyrrolidinium causes retention of salt and water in the organism In a few cases this retention may cause latent heart failure to become manifest, as hydræmia, pulmonary congestion, dyspnœa at rest, and œdema develop, but in the great majority of cases it produces no symptoms My 3 patients were on the border of incompensation already before treatment, so possibly it is only in such patients that pentapyrrolidinium may produce symptoms of circulatory stress

This condition is undoubtedly not harmless, especially if it is not recognised The treatment can, however, be completed either by combining pentapyrrolidinium with mercurial diurectics (cases 1 and 2) or by reducing the dose of pentapyrrolidinium (case 3)

### Summary

The treatment of hypertension with pentapyrrolidinium causes retention of salt and water

In some cases this retention of salt and water may cause relative heart-failure to become absolute This happened in 3 of about 100 hypertensives treated with pentapyrrolidinium All 3 patients were on the border of incompensation before treatment

Such cases can be found by frequently weighing the patient in the early stages of treatment, and this trouble some complication may be avoided by administering mercurial diuretics or by reducing the dosage of pentapyrrolidinium

Messrs May & Baker Ltd supplied the pentapyrrolidinium *compounds*

" Big buildings are not new But in the big buildings of tradition—the churches, the castles the city halls—it was each part that was big, and the impressiveness of the architecture depended on this Moreover, the large elements in the design represented large spaces inside Our new, big buildings are different They are composed of relatively small parts multiplied almost indefinitely And the spaces inside them are small The repetition of more or less identical smallish units—flats or offices—is expressed externally by rows and tiers of identical windows Not only do these threaten a new monotony, but the swollen bulk of the buildings has a destructive effect on the townscape, all the more disturbing because their purpose—housing, finance, adminis n—does not entitle them to dominate over their dings as cathedrals and courts of justice—the symbols l organisation—can legitimately dominate over theirs "

RICHARDS *Listener*, Jan 6, 1955 p 18

# IMPOTENCE

## J F Tuthill

L M S S A, D P M
HONORARY PHYSICIAN, LONDON AND BIRMINGHAM M
GUIDANCE COUNCILS

SEXUAL impotence is generally regarded as a logical disorder, but it can be satisfactorily tre methods that are essentially *physiological.* To that it is caused by a failure in emotional relati and that treatment should be directed to a these relationships, is, I am sure, unwise

### Classification

There are only three ways in which sexual may fail (1) insufficient erection (in strength, fre *or duration*), (2) *premature ejaculation*, absence of ejaculation

### Erectile Impotence

*Causes*

Many people think that there is some a between men and women which should arouse th sexual desire at appropriate times, and that t something wrong with them, or their wives, desire is not kindled But the truth is that the stimuli to erection are all through contact Adu with growth and experience, and the conditioned reflexes, erotic sensation may be by a wide variety of stimuli and by *fantasy* basic stimulus is that of touch

Under natural conditions a young man nev intercourse His first contact with a woman casual or deliberately exploratory, but he step by step, by his urge for more satisfying stimuli, until he reaches a point when inter inevitable

*In a civilised society restrictions* are *placed* intercourse, opportunities for physical con reduced and the natural development of th instinct is thus delayed In theory developmen proceed naturally when restrictions are *rem* matrimony, but in fact marriage too often " must not " overnight to " must," and, thoug can at any stage say " I won't " without harm to he can never say " I will " without the risk, later, of failing

Nearly all the *failures can be traced* direct or other of our faulty cultural patterns Th represents sexual intercourse as a contest betw and woman, in which the aim may be said gain the highest score Another elementary there is a " right " type and amount of sexua for different periods of life and that those wh from it damage their health At a higher cult —*that of marriage manuals*—intercourse complicated psychophysical skill

Highest of all is the spiritual pattern and its shadow which ignore the physical aspect of teach that the act has no significance unless it panied by a spiritual or psychological union concerned here only with the physiology of with the use made by, or meaning given to any participants, but I must offer my when function is inhibited by *consciousnes* absence of exaltation, it is more likely to b by, so to speak, working from below *upwards* above downwards

*Treatment*

When intercourse has failed, the patient trying and retrace the steps of courtship, whic cases he may never have trod at all Most couples, in order to avoid a humiliating *situa* sensibly spend as little time as possible in *bed* the first problem is to persuade them to spend n time in bed together for spontaneous contact e place At the start a man cannot help feeling very contact is a signal for an attempt at inter and, as he does so his attention is diverted from nsual pleasure to its probable outcome and the il reflexes are inhibited proportionately After a he search for pleasure becomes his objective and gets that he is trying to achieve intercourse and g as he is occupied in exploring appreciating and ving on his contact sensations and perhaps inter ng them with erotic fantasies he cannot be worrying his impotence

h is the margin of potency in young men that many regular intercourse for years without being aware y sensual pleasure—the activity being kept on habit or a sense of obligation But in these circum s desire wanes early and when they come for nent they must still be retrained on the same lines ssence of treatment is the simple lesson that inter e is a sensual pleasure or nothing

st endocrinologists maintain that testosterone is olpful in cases of functional impotence On the hand erectile capacity is not a constant but is ed by stress worry or failure, and in such cases ncreased by giving testosterone

ll four years ago I used methyltestosterone by mouth esponse in about half the cases but since then I have implantation and in every case some improvement in on has followed. The effect of sublingual tablets is stant and even in the patients who respond it declines y are taken regularly In order to take a dose that may ective the man must decide some hours in advance when ll make an attempt and planning is the main thing I avoid

ming erections can be regarded as a reliable indication otile capacity being independent of the sexual situation, n every case where these are depressed I give an implant tween 100 and 200 mg of testosterone I insert 25 mg nts (2 2 mm. diameter) with a trocar and cannula th the skin on the outer aspect of the thigh using ml of Novutox for local anæsthesia No stitch uired.

eral of my patients who have had injections of testo ho elsewhere have reported that there was no response them, or that the response was too transitory to be of se

### *al Features*

no patients have had sexual fantasies or activities many would call perverted Inquiry for these l be made as a routine and since some men onceal such facts unless put completely at their have learnt to frame my questions in an encourag y The patients usually feel that their fantasy is abnormal and make a big effort to abandon it and ch their wives in a spirit of what they regard as love. However the fantasy may be so closely into their sexual reflex that they only succeed biting all sexual response

48 patients in this category whom I have seen een only masochists mild sadists fetishists and stists and I have told them that I think their fall within the normal range of variation I have them to keep their fantasies and bring them their ordinary sex contacts and I have made it at once satisfactory intercourse is established the s will fall into the background I was at first ed and disappointed at the success of this approach ntended only to give them first aid relief in a to situation and then settle down to learn ng of their individual psychopathology But now satisfied that such first aid is all they

ust be difficult for a man however good his lity to integrate a trait that is taboo in his section of society I cannot hold that because the effort to do so has caused a transitory loss of potency he therefore has neurosis Any quality that lies at an extreme of the range of variations may cause its possessor certain difficulties and the treatment of these patients consists essentially in widening their concept of the normal range of human qualities

## Premature Ejaculation

### *Cause*

This condition typically occurs in young well sexed men at the start of their marriage but occasionally it is the chief complaint of a man whose erections are failing and in these cases the treatment is that of erectile failure The usual story is that as a boy the patient had a strong urge to masturbation (The actual stated frequency is not significant because one cannot estimate the degree of restraint that he has exercised This restraint, which psychiatrists call "guilt" is usually based on by current standards perfectly reasonable moral scruples or on considerations of health or athletic prowess ) There was probably an ardent courtship, with involuntary ejaculations even on clothed contacts and, if there were attempts at intercourse before marriage they ended in a premature ejaculation which raised some degree of reasonable apprehension in the man s mind for the prospect on his wedding night

Difficulty in penetrating or in fitting a sheath may be an unexpected cause of premature ejaculation but the truth is that most men ejaculate very quickly when they first make a satisfactory penetration It is their reaction to this experience which determines whether or not they are to become premature ejaculators

The fortunate ones are those who find pleasure in the experience brief though it is they are eager to repeat intercourse, which they do until ejaculation is sufficiently delayed for their full satisfaction Since in the normal young man the capacity for erection always outlasts that for ejaculation this cannot fail to happen Experience stabilises the reflex, and though ejaculation will always occur more quickly after a period of abstinence, this does not constitute prematurity To those who ask how long should it last? the answer is as long as you want it to

The unfortunates are those who are abashed and lose their erection or decide that it is wiser to postpone a second attempt until the next day when inevitably the same thing happens So they delay again hoping that the trouble will settle down or that in time they will discover a successful method of restraint

If one of these men consults his doctor he will probably escape with a dose of phenobarbitone too small to impair his potency and an assurance that the trouble will improve in time His lot is easier than that of the man who reads marriage manuals and still further distorts the natural pattern of his intercourse by attempting techniques of restraint. Both are infinitely better off than the man who sees a psychiatrist and learns that his incompetence is the symptom of some hidden defect in his emotional life

Some of these men have such robust sex drives and such sturdy constitutions psychologically that their sex life persists for many years They derive little pleasure from it but they carry on to please their wives or out of a sense of self respect accepting their disability philosophically More usually though the intervals between attempts at intercourse gradually lengthen and erections fail early as is only to be expected of any activity which does not receive its physiological reward

These patients often complain that they are too tired for intercourse or feel exhausted after it The fact that normal men do not make these complaints has led some people to suppose that the tiredness is psychological It is on the contrary quite natural because such patient, to have intercourse, must make a great effort of restraint during the act, and find courage to face the disappointment and often his wife's exasperated tears when it is over

*Treatment*

Treatment seems too grand a word for telling a man to abandon all restraint and have more frequent intercourse, but that is all that is required Of 60 uncomplicated cases under 40 years of age, 51 reported that they were making satisfactory progress after a single visit and needed no further help, 5 were seen twice, and 4 between three and six times before the same result was achieved Difficulty in getting sufficient erection sometimes arises in older men and in long-established cases and this must be dealt with on the lines already described

Some men cling to the popular idea fostered by marriage manuals that a man can, or should, control the moment of his ejaculation This error must be responsible for a vast amount of suboptimal sexual function, for, while there are excellent reasons for planned control of sexual opportunities both restrictive and expansive according to circumstances, nothing is ever gained by detracting from the spontaneity of the sexual act itself There is in fact no way of delaying an orgasm during intercourse, and, if the claims of those who say they can do so are examined, it will be found either that they cease all movements or so much restrain them, that in effect they stop intercourse, or else that they are living so well up to their sexual capacity that they cannot ejaculate unless they make a special effort to do so The ideal of a simultaneous orgasm in the man and woman is usually achieved when the man himself needs the additional stimulus of the woman's orgasm to bring on his own

Not uncommonly a man reports after a few weeks that he himself is all right but that his wife is still without an orgasm Seeing that many women take several months to reach orgasm, even when married to a competent male, it is only to be expected that one who has been deconditioned by a husband with premature ejaculation should take much longer I always make this clear to couples and advise the husband to ignore his wife's reaction, for a woman's orgasm is like a man's erection—an involuntary reflex—and the more she strives the less likely is she to achieve it Above all, a husband should never ask If he is in doubt, the answer is "No," and asking only adds to the wife's difficulty by making it appear that their intercourse has been a failure Any woman's capacity for orgasm on one particular occasion is unpredictable Woman's orgasm depends more on the natural, unrestrained rhythm of intercourse than on the number of minutes penetration can be sustained without ejaculation For a man to attempt restraint is equivalent to trying to drive his car at full speed with the brakes on Men, like motorcars, do not last long under such treatment

Patients' replies to follow up letters show that the result is usually a gradual improvement, and the lack of a clearly defined end point may explain the failure of such a high proportion to report their progress The improvement, however, influences their whole relationship, and at least in their opinion, it has been related to the advice they were given rather than any "psychological" influences Thus a man who had been married two years said six months after his only visit "It's made my married life, it's like getting married again, we don't get on each other's nerves and we're more contented", and another "the treatment prescribed has been doing me a lot of good and I think I need not another appointment" As only half an hour is for the initial consultation, it would hardly be le to exert much psychological effect

## Absence of Ejaculation

Any man may on occasion fail to ejaculate beca short a period has elapsed since he last did so, or he is not getting enough stimulation from the activity in which he is engaged But a small prop of men (about 3% in this series) have never during masturbation or intercourse, though ther experienced nocturnal emissions

If it were practicable to standardise cond measure the average time taken for ejaculation by a of men, and plot it against the numbers of men time period, the result would no doubt be a curve resembling the curves obtained when the d tion of any other variable natural quality, such as or intelligence, is similarly recorded The qualit measured in this case would be the natural exci of the spinal cord reflex are concerned

*Cause*

The most important factor in lowering the exci of this reflex is age Kinsey's observation that fr of orgasm declines before full maturity is reached s that reduced excitability rather than any def potency is the cause It is probably significant th average age at which the first attempt at took place was 32 years for this group as ag years in the other cases

All except 1 was physically and psychologicall they had good employment records and had adjustments in their marriages despite their The exception differed only in being a very s chistic fetishist who had married at 43 He co originally of erectile impotence but was fully coöp in treatment and became potent only to find eja was still beyond his reach

*Treatment*

One's scope for increasing excitation is limited advice on technique, including the employme fantasies, and the application of a vasodilator, s 'Trafuril,' to the penis may help Of the various cological remedies, I have found a proprietary containing amphetamine sulphate, strychnine, and yohimbine the most helpful in bringing near to orgasm, though never to success Oestr was ineffectual Testosterone revives erection increases sexual excitability generally and the of semen, but I have seen no direct success from

2 of the successful cases are reported below and 8), the 3rd only needed advice on techn 4th man is worth mentioning because he had alre successful by the time of his appointment

In terms of improved technique there was no exp He was 31 at the time of his marriage and first and for the first four months he succeeded in ex masochistic fantasies on which his sex life had form This left him with sufficient erection for pene checked ejaculation However, after making his a the fantasies broke through and he immediately A feeling of disquiet at their persistence was the his visit

## Results of Treatment

The following figures, based on a postal various intervals after treatment, give a gene the series, and the results, on which this based

| Disability | Did not reply or not treated | Failed | Satisf with impro men |
|---|---|---|---|
| Insufficient erection | 97 | 18 | 130 |
| Premature ejaculation | 96 | 2 | 107 |
| Absence of ejaculation | — | 6 | 6 |

## Illustrative Cases

ase 1 —A clergyman aged 32 had been married nine rs. As an undergraduate he took his work very seriously ried about philosophical problems, became depressed attempted suicide While still at the university he met -wife and passionate desires developed so they thought it ıt to get married; but being unable to support children y decided that their contacts should stop short of inter rse. This was not attempted until about eighteen months r marriage when he had difficulty in penetrating ejacu d prematurely and failed He was advised to have chological treatment, but this had no effect on his sexual acity

his man's history included a depressive episode and ral major inconsistencies. But his personality com ded respect and it was a far less serious matter to ask to make some temporary concessions toward sensual lgence than to probe his psyche if one had the pre ption to do so; or to question the guilts and anxieties h must anyhow afflict a young man of his temperament unately his wife was one who could manage the para ical situation of stimulating his desire without appearing sk anything for herself He was given the usual advice an implant of 100 mg testosterone and two months was successful after six visits. He wrote eighteen months to say that they had a baby and everything was factory

ase 2 —This man, aged 28 had been married two years ıad completed a pilot's training but the war ended before ad flown many hours. On demobilisation he went on the o and worked hard in repertory companies; but seeing uture for himself had found an opening in business, and due to start in a month. He had a lively responsive onality and was active and intelligent. He had no guilt it masturbation but on the half-dozen occasions he had intercourse before marriage (not with his wife) he had felt at ease and though he never failed he had not ed much pleasure. His wife had started menstruating heir wedding day and the strong erections with which d started began to fail before he could begin intercourse till had erections on waking and on contact with his wife hey failed every time before penetration His intelligence his temporary unemployment (without financial stress) him an ideal patient. If the method was right he must ed He was therefore told that if he did not write in days he would be sent a second appointment to come his wife As no letter came the appointment was sent e last minute Fortunately the residual disability was letter writing He wired immediately: Interview essary machine functioning delighted and grateful ng

se 3 —A bank official aged 38 had been married two and had a son a year old. As a boy he had masturbated three times a week, and later he had had involuntary ations on contact. When he had intercourse it never more than three or four thrusts Intercourse had occurred more than once a night since his marriage e felt so ashamed that for some time it had sunk to once th He wrote three weeks after his visit following your and my wife's visit to Dr L. (to whom I had referred contraceptive advice) there has been a marked improve in our sexual relationship We found the cap a benefit but no doubt the main advantage was a more stic outlook on the question

cord this case in fairness to any critic who maintains ny treatment is really psychological It is inevitable patients should experience feelings of optimism onfidence once they can see clearly a way out of grievous difficulty But as the bottle of medicine ses their evidence is not reliable

e 4 —A 16 stone docker (aged 28) of enormous strength en three years married and had a daughter of 18 months. a typical mesomorph with an amicable disposition and tioning self-confidence He had never consulted a nor would he have done now if his young wife had not ferred to a gynæcological department when her lack al satisfaction was discovered He himself did not his sexual history was a proper subject for inquiry but ured that puberty was early and that street-corner intercourse started at 15 He regretted that his wife had no enthusiasm for intercourse but did not suspect that there was anything wrong with him. Were you too quick? Dunno 'How many thrusts? About three or four

He came back in four weeks. At first he had had intercourse as many as four times in succession; it lasted ten minutes and his wife had had several orgasms Though inarticulate he was very grateful

Case 5 —A wood machinist aged 23 had been married for eighteen months. His case is included because it illustrates the universal neglect of proper inquiry into sexual function and the way in which failures from other branches of medicine are accepted for treatment by psychiatrists

His trouble was pruritus ani which started a few weeks before his marriage Despite thorough dermatological treatment it persisted and he was accepted by a psychiatrist and passed to me for treatment The psychiatric notes gave no indication of the probable trouble but said that he was emotionally unstable and rather tense Sexual function was noted as being normal though the patient said that he had mentioned that he always reached orgasm before his wife and had been advised to restrain himself

The sex history was typical. Puberty early; a strong urge to masturbation, sometimes gratified twice daily despite guilt He had been physically interested in women since he was nineteen, and was liable to involuntary ejaculation on clothed contact He had married after demobilisation and had had intercourse three times a week since He felt this was the most that he could safely indulge in yet despite the maximum restraint he rarely reached a dozen thrusts before ejaculating

He accepted my usual advice and three weeks later reported that he had had intercourse almost every night and that it now lasted the full time" The irritation was very much less. By the end of six weeks he had settled down to five nights a week the itch had disappeared and only faint traces remained in the skin. He and his wife felt fully satisfied

Case 6.—This was a successful professional man of 35 he had married at 30 and had a son 2 years old He was very hard working sensitive and most considerate of his wife.

Puberty was at 13 and soon afterwards his father told him ' all about things and said it was a bad thing He never masturbated He first had intercourse at 21 He was always quick the first time but usually had two or three ejaculations at a time and both partners were satisfied until his wife became pregnant Intercourse ceased early in pregnancy owing to threat of miscarriage and when it was resumed four months after the birth of the baby he was very quick. His wife then had little desire and was upset by his premature attempts Twice when they were first married her cervical cap had been extracted with difficulty by a doctor so they would not use it He found sheaths troublesome He developed a gastric ulcer and was in bed for six weeks and his wife had been " under the doctor ever since her confinement.

He came again six weeks after his first visit but was no better The contraceptive trouble had been settled but his wife had no enthusiasm and he felt that her health forbade repeated intercourse while her lack of welcome damped his ardour

This common vicious circle infrequent intercourse—premature ejaculation—lack of satisfaction—diminution of desire—infrequent intercourse can be quite troublesome to break but eight months later he replied to a follow-up letter: The relationship between my wife and I has improved immensely "

Case 7 —An accountant aged 28 had been married three years Puberty was at 12 and he had had regular physical contacts with good erections and enjoyable sensations since adolescence He had regular intercourse for the first two years of his marriage but he never ejaculated except during sleep He had several months psychological treatment without avail and was given a hopeless prognosis by a recognised authority His wife badly wanted a child and gave full range to her disappointment in tears tantrums, and reproaches. When he was first seen his erections were poor and in intercourse rarely occurred. An implant of 150 restored his erections and gained a spell of his wife but despite every effort the orgasm him. He noticed however that nocturnal followed attempts, so he was given a Malleson artificial insemination syringe and advised the days on which conception was most probable Sexual activity was kept going for six months in the hopes of achieving a pregnancy in this way with little expectation of any other result

Then, one evening whilst watching television (he said bored not stimulated by it) he had the desire for intercourse and it took place in the sitting room (I think this is significant as illustrating the importance of spontaneity to both partners ) His wife was more than usually responsive, their movements rapid and synchronous, and he ejaculated He has continued to do so ever since and his wife is now pregnant and contented

**Case 8**—A Civil Servant, aged 28, had only been married five weeks He had a generalised ichthyosis and had suffered from a prolapsed disc Since the age of 16 he had had physical contacts with erections but had never attempted intercourse before marriage or had any ejaculation except in sleep His main complaint was absence of ejaculation, but he had a lot to say about his lack of agreeable sensations

Never having succeeded with one of these cases at that time, I did not welcome him and can only remember that I chided him for his superficial approach Not until I was going through the records seven months later did I notice that he had cancelled his second appointment ten days after his visit, with a letter to the clinic thanking me for "sympathetic and helpful counsel" Thereupon I wrote asking what advice I had given him and in what way it had been helpful, to which he replied

> 'I have indeed overcome my little trouble thanks to your help You may remember that I had no difficulty in achieving erection but I came to you with the question What is the point ? I thought I was supposed to enjoy it' On your advice I forgot about enjoyment and set out merely to find what pleased my wife This resulted in my performing the normal movements of intercourse without taking any interest in it at all, but I found that she responded at once It all ended in an ejaculation which seemed to last only a second or two and although enjoyable didn't seem to me to justify the effort However there was a starting point and using my wife's reactions as a guide to speed I performed this artificial process fairly regularly It was a case of pleasure by proxy because my main enjoyment came from a sense of power as I found myself able to give pleasure
>
> "As you said I would, I have gradually acquired a taste for this business and now I enjoy it from beginning to end"

**Case 9**—Sexual fantasies based on immature girls had worried a solicitor aged 32 since adolescence He had never indulged in any contact or, even in imagination, wanted intercourse He married at 28 without any previous sexual experience, but intercourse was precarious from the start and he tried to halt its decline by getting his wife to substantiate his fantasies in speech and dress This was not successful, he became completely impotent and failed in two jobs. His wife had just left him and started proceedings for mental cruelty

He was told that his fantasies were probably shared by a fair number of pubertal boys and later abandoned as opportunities for contact with older girls came along It was his misfortune that a shy, sensitive nature and careful upbringing had denied him these opportunities His mistake was trying to exclude the fantasies and then later to enact them He should have taken them to bed with him and in time they would have receded

Notwithstanding that he saw his wife the next day and allowed her to get the gist of my advice from him (receiving in exchange some blistering comments on my depravity), she returned home Intercourse restarted and they both experienced greater satisfaction than ever before He said that apart from the recovery of his potency he felt a completely new man so great was the load now off his mind

Was he right ? Or is he still a psychological mess whom I should have left impotent so that I could have pulled his psyche to bits and rebuilt it ?

## Conclusion

There seem to be only two possible primary causes for sexual impotence The first and generally accepted view is that it is psychological, the result of faulty personal relationships, and that therefore the first object of treatment must be to unravel and readjust these The alternative view which I have tried to put forward is that the primary cause is a faulty development of the [illegible] reflexes, due fundamentally to the restraints of [illegible] Naturally these restraints react on the more sensitive men, and inevitably, once impote established, secondary stresses arise between and wife These stresses may take up so much picture that they appear to be the primary ca may sometimes be that the resolution of these allows the natural force of recovery to succeed

I suggest that psychological investigation is indicated until one is satisfied that physiological re ments are fulfilled It has been my experience th this is done nothing more is needed

It would be wrong for anybody to conclude just because social restraints sometimes cause in susceptible men these restraints should be For one thing there is no way of knowing wheth not impotence is a serious problem in the populat large, and for another there is still much to be l about the effect on society in general of such Better sex education within the existing limits probably have prevented all the cases I have but it would have to be on different lines from th any of the existing marriage manuals

The writings of Gesell, Sheldon, and Kinsey prov background for this work But for the force that swimming against the tide for five years without ad I am indebted to the rigorous training, in making an on my own observations, which I received fifteen yea Charing Cross Hospital from a neurologist to whom I very grateful

# TORSION OF A FALLOPIAN TUB

T M ABBAS
M D Edin, F.R C S E, M.R C O G
LECTURER IN OBSTETRICS AND GYNÆCOLOGY IN
UNIVERSITY OF SHEFFIELD

TORSION of a fallopian tube is rare and is sel ever, diagnosed preoperatively, because it prod pathognomonic symptoms or signs This is es true when the tube is known to have been in the case reported here

The first case was published by Bland Sutton (18 Régad (1933), reviewing 201 cases of torsion, fou in 24% *the tube had previously been apparently* heal 18% *it was a hydrosalpinx*, in 14% it was part of a in 13 5% there was infection, tumour, or ectopic, and in 12% there was an intra uterine pregnancy

Torsion during pregnancy was fully reviewed by (1936), who gathered 13 previously published cases an 1 of his own, and Caldwell (1949) and Kushner and baum (1952) have since reported similar cases Mu (1948) described a case of torsion of a previously healt in a non-pregnant woman

Reviewing the ætiology and mechanism of torsion, Blum and Sayre (1937) discussed many and examined the influence of anatomical malform peristalsis of uterus and tubes, venous engorgeme sudden body movements in initiating torsion presence of disease

The predominating clinical feature is sudden pain in an iliac fossa, associated with localised and tenderness and usually nausea and vomitin temperature is usually normal Tachycardia present Uterine bleeding, which follows the pain, is presumably due to pelvic congestion T be compared with the absence of bleeding shortl torsion of the pedicle of an ovarian cyst Sy referable to the *urinary tract* (McKerrow 1934) or alimentary tract have been observed The severit symptoms depends on the degree of torsion, the of interference to the blood-supply, the extent of (Anderson 1945), involvement, if any, of the and the extent of venous thrombosis

The similarity of the symptoms to those of pregnancy, a small twisted ovarian cyst, salp dicitis mesenteric lymphadenitis and strangulated make accurate preoperative diagnosis difficult cases collected by Savage (1936) and his own case nisdiagnosed A helpful diagnostic feature is the ce of intraperitoneal serosanguineous fluid com le with that found in early cases of ectopic gestation be found by aspiration of the pouch of Douglas

## Case report

arried woman aged 32 who had borne one child was en and admitted to the Jessop Hospital for Women ld, on June 8 1954 with the history that on June 6 d a sudden attack of colicky intermittent pain in the ac fossa and radiating to her back and down the lateral of her left thigh. She felt nauseated and vomited The pain was followed shortly afterwards by vaginal ng, but the loss did not cause any worry because this bout the time of her expected menstrual period She l that menstruation had always been regular 5 28 at the last monthly period which had been quite normal n May 11—28 days before admission

*examination* she was pale with pulse rate 100 normal rature and blood pressure 120/75 mm. Hg Her en was slightly distended rigid and tender in the left quadrant there was no evidence of shifting dullness ination per vaginam showed a normal anteverted mobile s and normal right tube and ovary There was, however tenderness on movement of the cervix and a tense r mobile swelling as big as a plum was palpable to the of the uterus. Either ectopic gestation or a twisted an cyst was provisionally diagnosed though the signs ymptoms were not altogether typical of either condition on of the tube was not considered.

*ration* —Under general anæsthesia the above mentioned gs per vaginam were confirmed and on aspiration e pouch of Douglas some faintly bloodstained serous with crenated red cells was obtained At laparotomy the neal cavity contained about 8–10 oz. of fluid similar at removed by aspiration. The uterus and right adnexa ared normal (the right ovary contained a recent corpus m) The left fallopian tube however had undergone ckwise twist of 540° and was distended with blood The vary appeared healthy apart from some exudate on its e The left tube was removed

*stoperatively* recovery was uneventful and the patient discharged on June 22 Seen on July 20 she was in good *h and said she had menstruated normally on July 14*

*hology* —The specimen removed at operation was a ian tube whose proximal part appeared normal and part dilated to 1 inch in diameter The fimbriated end bliterated by partially organised clot Section of the d part revealed blood-clot in the lumen and hæmorrhage wall Histologically apart from the extravasated blood artial tissue necrosis, there was no evidence of pregnancy ere any chorionic villi seen in the clot The condition hat of hæmatosalpinx due to torsion in an apparently y fallopian tube

## Discussion

is case is a typical example of hæmatosalpinx o torsion of a healthy fallopian tube The chief s of interest are as follows

The cause of torsion as in most of these cases, is wn but pelvic congestion brought about by the approach enstrual period may have been a factor

The original diagnosis was erroneous.

Uterine bleeding following on the torsion was probably secondary vascular engorgement a common finding o gynæcological complications.

Although aspiration of the pouch of Douglas did not lish the diagnosis it was of real assistance in the decision arotomy

*Conservation of the ovary on the affected side was* le even though the tube had undergone a twist of 510

## Summary

ase is reported in which torsion occurred in a usly healthy fallopian tube

In many cases the cause of the torsion is unknown but pelvic disease appears to predispose to this accident

Torsion of a fallopian tube can seldom if ever be diagnosed before operation, but symptoms and signs similar to those of torsion of a small ovarian cyst with the addition of immediate uterine bleeding should bring the possibility to mind

Aspiration of the pouch of Douglas should produce evidence similar to that found in early ectopic pregnancy

The decision regarding whether the ovary can be conserved or not must necessarily be made at laparotomy

I should like to thank Prof C S Russell for his permission to publish this case and for his helpful criticism and advice

# TORSION OF THE TESTICLE

BETTY M L UNDERHILL
M.A B.Sc Oxfd M B Lond F R C S
REGISTRAR, CHASE FARM HOSPITAL, ENFIELD MIDDLESEX

THE clinical picture of torsion of the testicle is characteristic and descriptions of it vary very little Aird's (1940) account is representative There is sudden pain nausea vomiting swelling of the testis and usually an effusion in the tunica vaginalis The agonising pain particularly impressed Lambert and Smith (1938) when they surveyed cases in boys at Rugby School and Walton (1952) states that pain redness swelling, and œdema are always present in such cases

The following case is of interest because it showed not one of these features

## Case report.

A man aged 23 was admitted to Chase Farm Hospital on Aug 31 1954 with six days history of a slightly tender swelling in the right inguino scrotal region He had had a little pain scarcely more than discomfort, in the swelling and in the lower abdomen but it had not been severe enough to keep him away from work He had not had nausea or vomiting and his bowels had been open regularly The day before admission he had experienced some discomfort on walking and consulted his doctor who diagnosed an inguinal hernia in danger of strangulation and sent him to hospital The symptoms had abated in the twelve hours since he had seen his doctor There had been no inguinal swelling and the testes had both been in the scrotum before the onset of this episode He had neither strained himself nor injured his scrotum

*Examination* —He was thin and pale a poor witness and of low intelligence He was quite comfortable with a clean moist tongue and a temperature of 97 8°F and pulse rate 88 On the right side there was a tense and slightly tender mass measuring about 3 inches by 2 inches, in the inguino scrotal region. The overlying skin was normal in colour and temperature The mass did not allow transillumination and there was no impulse on coughing The testicle could not be felt separately from the swelling and the scrotum hung considerably lower on the right than the left Sensation in the left testicle was normal There was no abdominal tenderness or swelling and rectal examination revealed only soft fæces Normal bowel sounds were present An obstructed inguinal hernia was diagnosed The possibility of testicular torsion occurred to the admitting officer who rejected the diagnosis because he had had the condition and he feelingly contrasted his own agonising sensations complete comfort of the patient before him

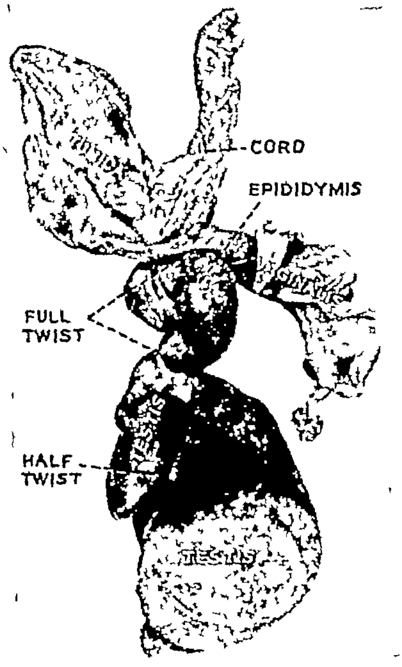
*Operation* —About six hours after admission local anæsthesia was induced with $1/2$% lignocaine, and a right oblique inguinal incision was made The inguinal canal contained only a slightly œdematous cord, and the swelling consisted of a purple testicle and epididymis in the tunica vaginalis The mass was delivered out of the scrotum, and the tunica was opened A few ml of fluid escaped The body of the testicle was twisted on itself through a half turn There were further complete twists between testicle and epididymis and at the proximal pole of the epididymis The whole testicle and epididymis were gangrenous Orchidectomy was performed, and the incision was closed A small drain was left in the scrotum and removed after forty-eight hours

*Postoperatively* progress was uncomplicated, and the patient was discharged on the eighth day with his wound completely healed The Wassermann reaction was negative

## Comments

It is not uncommon for a maldescended testicle which has undergone torsion to be diagnosed as a strangulated inguinal hernia, but this testis, according to the patient, was fully descended Epididymo orchitis is the more common misdiagnosis of the lesion when the testis is normally placed, but this patient had little swelling, no redness, no pyrexia, and only slight tenderness

Hamilton Bailey (1936) says that torsion cannot take place in a normal testis Complete and high investment of the testis and epididymis by the tunica vaginalis enables the testicle to rotate freely within its enclosing sac Such a high investment was present and can be seen in the accompanying figure, but it is difficult to understand how this could have influenced the twist in the body of the testis and that between the testis and the epididymis



**Operation specimen The parts were identified histologically (Two-thirds of actual size.)**

It has been said that a scrotal abnormality is likely to be bilateral, and after torsion has taken place on one side it is wise to fix the contralateral testicle Ewert and Hoffman (1944), however, found that bilateral torsion had taken place in only 26 of the 489 published cases they were able to collect It therefore seems justifiable to keep this patient under observation and to operate only if symptoms arise It is essential that he should report to his doctor and be sent to hospital immediately if any scrotal discomfort or swelling develops

Thanks are due to Mr Max Pemberton, under whom the patient was admitted, for permission to publish

# TORSION OF THE OMENTUM

NORMAN C COOPER,
M.R C S

SURGEON TO WESTON SUPER MARE GENERAL HOSPIT
SOMERSET

CASES of omental torsion are rare enough, following 4 came under my care in the short eight weeks, and all of them were associated œdema of the peritoneum and abdominal muscles, complication I cannot find reported anywhere

## Case-reports

**Case 1** —A man, aged 31, was admitted on March with twenty four hours' history of pain in the fossa, unaccompanied by nausea and vomiting, and hours history of diarrhœa

*On examination* his pulse rate was 68, respirations temperature 98°F His tongue was clean, and there fœtor oris His abdomen was soft and moved on and bowel sounds were heard His right iliac fossa resisted pressure, and showed rebound tenderness examination was negative

*Operation* —The abdomen was opened through a incision, and the oblique muscles were found to be and the peritoneum thickened When the perito incised, bloodstained fluid welled up The normal, but the greater omentum was swollen, thickened down the lower three quarters of its right which had rotated clockwise, but the number of not be assessed No cause for the rotation The affected portion of omentum was resected abdomen closed The patient's postoperative reco uneventful

**Case 2** —An obese retired sea captain, aged 73, ted on March 15 to Burnham on Sea Hospital with hours' history of lower abdominal pain He had once, and the pain was greatest in the right iliac over the right external abdominal ring

*On examination* his pulse rate was 80, respirations temperature 98°F His tongue was clean, and there fœtor oris His abdomen moved normally, but exquisitely tender at the outer border of the right abdominis muscle, where an indefinite mobile be felt

*Operation* —A right paramedian incision was made an œdematous abdominal wall When the peritone opened, a large quantity of bloodstained fluid and the mass was obviously greater omentum abnormality was found in the abdomen, and there adhesions of the greater omentum either to abdomina contents and no herniæ The lower border of the omentum was almost gangrenous and twisted clock times on its long axis The affected portion was by serial ligation proximally and resection The recovery was uneventful.

**Case 3** —A male clerk, aged 22, was admitted with five days' history of pain to the right of his This had persisted up to the time of his admiss it had moved to his right iliac fossa and become had had nausea but no vomiting Slight diar been present on the third day He had bee weight

*On examination* his pulse rate was 98, respiratio temperature 98 6°F His tongue was clean, and no fœtor oris His abdomen moved normally on and bowel sounds were heard The right iliac fo tender and resisted palpation Rectal e negative

*Operation* —Laparotomy was done through a incision, and the oblique muscles were found to be and the peritoneum much thickened Bloo was present in the abdominal cavity The normal, but a thickening was felt higher up, to be in the greater omentum, which had a thick coloured right border which had rotated clock affected portion was ligated and resected, and closed. The patient's convalescence was unevent ase 4.—A girl aged $5\frac{1}{2}$ years, was admitted on May 11 [illegible] five days history of stomach ache followed by pallor [illegible] pain became acute just before admission and was [illegible] ralised over the abdomen. There was no vomiting but [illegible] sea was present. The bowels had acted regularly and [illegible] had been no urinary symptoms

[illegible] *n examination* her pulse rate was 120 respirations 25 temperature 100°F There were no signs in her chest or [illegible] ral nervous system. Her abdomen moved normally on [illegible] ration but there was much tenderness with guarding in [illegible] right iliac fossa. Rectal examination revealed hard [illegible] but no tenderness

*[illegible] peration*.—My house-surgeon (Dr M Ree) *opened* the [illegible] omen through a McBurney's incision and noticed that the [illegible] oneum was thick and œdematous. The abdomen con[illegible] d sanguineous fluid and the greater omentum was black [illegible] thickened down its right border which was twisted [illegible] cwise A few rubbery glands were present but otherwise [illegible] ing abnormal was found The twisted omentum was [illegible] ted the appendix removed and the abdomen closed [illegible] patient's postoperative recovery was rapid

### Summary

[illegible] cases of omental torsion occurred in eight weeks [illegible] men and 1 in a girl. The youngest patient was [illegible] years (I have not heard of this condition at so [illegible] an age) and the oldest 73

[illegible] cases were of the primary (Payr's hæmodynamic [illegible] on) type all affecting the right free border of the [illegible] ntum The 4th (case 2) was a lesion of the lower [illegible] er of the greater omentum In all the rotation was [illegible] kwise.

[illegible] l 4 cases presented signs suggesting appendicitis but [illegible] was no furring of the tongue or fœtor of the breath, [illegible] except in case 4 there was neither pyrexia nor rise [illegible] ulse rate.

[illegible] ne feature common to all which I cannot find [illegible] tioned in any published report, was œdema of the [illegible] minal muscles and peritoneum The presence of [illegible] former tempted one to make a diagnosis before the [illegible] toneum was opened

[illegible] no case was an obvious cause for the torsion found

---

## Preliminary Communication

### IE EXCRETION OF PHOSPHOETHANOLAMINE AND HYPOPHOSPHATASIA

[illegible] E have during the past year been studying some [illegible] of infantile and adult hypophosphatasia In [illegible] tion to the changes in the bones and tissues that [illegible] been noted by others we have made an observation [illegible] has not so far been reported As increasing attention [illegible] ing paid to hypophosphatasia by physicians and [illegible] iatricians we have decided to report our observation [illegible] y so that others interested in this aspect of the [illegible] se may study it on their own cases.

[illegible] ine obtained from a two month-old male child [illegible] ing from hypophosphatasia and which showed the [illegible] rachitic bone changes hypercalcæmia and a [illegible] lkaline phosphatase in the serum was subjected to [illegible] partition chromatography for amino acids. A [illegible] orresponding to that for phosphoethanolamine was [illegible] No corresponding spot for ethanolamine was [illegible]

[illegible] phosphoethanolamine can act as a substrate *for the* [illegible] ne phosphatase, the excretion of this *substance* [illegible] ine of these patients appears to us to *be of* [illegible] and to indicate one way in which their [illegible] be deranged

### ROYAL SOCIETY OF MEDICINE

### The Future of Neurology

A MEETING of the section of neurology was held on Jan 6, with Prof F J NATTRASS the president, in the chair

Sir FRANCIS WALSHE F R.S made a plea for a more realistic approach in neurological research The primary responsibility of neurologists, he said, was to seek the cause of illnesses and find ways of curing and preventing them could it truthfully be claimed that present research was directed effectively to this end ? Nobody disputed the value of the contributions made by the neuro anatomists and neurophysiologists but, despite a century of nosography and morbid anatomy, the cause of disseminated sclerosis motor neurone disease and the metabolic disorders of the nervous system remained undetermined and we were as far as ever from finding a cure for them

The fruitful investigations of the pioneer physiologists had led later workers to assume that study of the anatomy and physiology of the nervous system would inevitably yield an answer to every ætiological and therapeutic problem. This belief persisted even today, as was shown by the eagerness with which the younger generation of neurologists had seized upon the new diagnostic electronic devices Yet it had to be conceded that in the last twenty years all major advances in treatment had resulted from chemical studies—studies made moreover, not by clinical or experimental neurologists but by workers concerned only incidentally with nervous diseases. Thus though the symptom-complex of subacute combined degeneration of the cord was identified in 1900, not until twenty-six years later did workers—outside neurology—determine [illegible] ætiology and provide the effective remedy ; and many similar instances could be cited

"All around us in medicine," said Sir Francis, "[illegible] find physicians working in chemistry and biochem[illegible] or in any discipline that may be needed to elu[illegible] the medical problems upon which they are eng[illegible] and it was nothing less than [illegible] and lack of vision that had prevented [illegible] from [illegible] same To regard n[illegible] as concerned [illegible] mainly with what could be seen in a micr[illegible] post mortem room was [illegible] this time to ta[illegible] and obsolete view

Welcoming the Medical Research C[illegible] creation of [illegible] to enable young [illegible] train for three [illegible] relevant sci[illegible] Sir Francis said [illegible] was an ex[illegible] of admi[illegible] which [illegible] needed. [illegible] was [illegible] neurolog[illegible] of the Royal [illegible] who [illegible] defined [illegible] training [illegible] the basic [illegible] some time work[illegible] possibility [illegible] Sir Franci[illegible] was to [illegible] and was [illegible] [illegible] PATLING [illegible] to [illegible] The [illegible] extent to which it assimilated contemporary discoveries in the laboratory, and on its ability to induce scientists to undertake the investigations likely to prove most profitable to practical medicine A great present need was for the re establishment of close and productive relationships between medical men and scientists

In the advance of medical knowledge there had been little in the way of any organised attempt to distinguish between major and minor objectives, or to estimate the adequacy of the available resources For instance, how many investigators were engaged in unravelling the pathogenesis and chemistry of the demyelinating diseases, which all agreed were fundamental problems in neurology? The failure to assess the relative importance of the many problems which confronted us was one of the most serious deficiencies of modern medicine As a result, the none too large resources of medical and scientific investigation were being dissipated over matters of lesser consequence

Referring to neurophysiology, Professor Payling Wright asked whether there was justification for letting the study of the biophysics of neurones absorb so much of the resources of neurology Attention might be paid more profitably, he believed, to the vessels of the central nervous system and to the cells of the neuroglia, and he urged that younger investigators be encouraged to inquire into the obscurity that still envelops the reactions of the nervous system to drugs and allergens, as well as into the biophysics and biochemistry of its tissue fluids Biochemistry, in particular, seemed to him the discipline most likely to infuse neurology with new and productive ideas, though the peculiar difficulties associated with the biochemistry of nervous tissues admittedly acted as a deterrent to workers in this field However, the introduction into biochemistry of the physically recognisable isotopes had provided medicine with an exceptionally powerful technique for exploring metabolic processes As a result, investigations could now be resumed into the hitherto baffling problems of the synthesis and breakdown of brain lipids—a field that had remained almost untouched since Thudichum and his followers had been forced, through exhaustion of their technical resources, to relinquish their pioneer studies

The future of neurology, Professor Payling Wright concluded, lay not in the isolation of problems and investigators but in the closer intellectual collaboration between those who saw and appreciated the important problems and those who could bring expert knowledge to bear on their solution

In the discussion that followed, Dr W **Ritchie Russell** drew attention to the serious shortage of neurologists throughout the country, and particularly in London He thought that, since the best facilities and opportunities for research were to be found in the universities rather than at Queen Square, what was needed was first to build up these university centres

Mr D W C **Northfield** pointed out that under the National Health Service little or no provision had been made to enable neurologists—or, indeed, specialists in any branch of medicine—to combine routine clinical duties with research He proposed that influence should be brought to bear upon those who arrange the National Health Service to make this financially possible

Referring to neurosurgery as the "naughty child" of neurology Mr **Wylie McKissock** said that the tables had lately been turned and it was the neurosurgeons who were now "repressing" the neurologists This policy was far from wise for neurology to advance, it needed to go hand in hand with all its associated branches, [illegible] ing the basic scientific disciplines He strongly [illegible] ted that a neurologist should always be appointed [illegible] r a neurosurgical team was established Dr [illegible] **Williams** agreed that the greatest benefits to neurology would result from workers in various rel departments of medicine collaborating in teams, he thought that new discoveries would have to c first from the fields of chemistry and physics before t could be much progress in neurology He remind audience that three biochemists supported by the Me Research Council were now working at Queen Squar

Summing up, Sir **Francis Walshe** reiterated his c tion that a fruitful future for neurology lay rather experimental pathology than with electrophysiol studies In the case of the latter it seemed that studies revealed more about the properties of the tus used than of the functions of the nervous sy

## Reviews of Books

### Prefrontal Leucotomy and Related Operations

*Anatomical Aspects of Success and Failure* A **Meyer**, M D Bonn, professor of neuropathology, I tute of Psychiatry, Maudsley Hospital, Lond **Elizabeth Beck**, research assistant, Institute of Ps atry, Maudsley Hospital, London Edinburgh & Boyd for the William Ramsay Henderson 1954 Pp 60 10*s* 6*d*

Based upon the William Ramsay Henderson le delivered by Professor Meyer in Edinburgh in 1 this book surveys anatomical investigations carried at the Maudsley Hospital on brains of leucotom patients who survived the operation long enough the result of the treatment to be judged. It is on 102 cases, of which 62 were histologically investigated—the largest group hitherto collected handling of this material was masterly, the planni the pathological procedure admirable, the investi systematic and painstaking, and the inte careful Since the patients were examined and in many hospitals and observed by various people different standards, conclusions could only be dr with caution Still, it was possible to give some an to one of the most controversial problems—namely, h much the clinical result was influenced by the quan of frontal lobe isolated, and how much it depended the locality of the operation There was consider more frontal-lobe interference

> "in the 24 much improved or recovered cases, as comp with the unimproved group This, of course, does not that the more of the frontal lobe is cut the better will be results, but it does mean that the cut must be adequ order to be effective While the quantitative factor retains its importance, a few facts have emerged which to some regional localisation The dorsal and, in part the dorsolateral sectors of white matter do not appear as significant for improvement as the mid central, and cingulate sectors On the other hand involvem the dorsolateral and lateral white matter, and partic cortex, appears to be one of the factors responsible personality change"

In correlating anatomical and clinical data the au come to the conclusion that cutting of the medial sector of fibres gives the best results in leucotomy also that the quantity of fibres removed in this seems to be important By studying the r degeneration in cells and fibres, they clarified ana problems which have hitherto been controversial, instance, they established that the magnocellular p of the dorsomedial nucleus and the anterior nucl the thalamus project into the medial orbital region that these nuclei receive fibres from the hypoth The granular prefrontal cortex sends fibres to the d medial nucleus of the thalamus only, and also a contingent to the hypothalamus and the pontine n Most of the efferent fibres originate from the agra cortex and end in the ventrolateral nucleus of the mus, corpus striatum, hypothalamus, red nucleus pons Fibres originating in the premotor parts of orbital region *and* in *premotor area* 6 end in v nuclei of the hypothalamus, the ventromedial nu of the hypothalamus seems to be the most impo end-station Schematic drawings illustrate the co cal connections, and an appendix tables the entire terial with the relevant clinical and anatomical he book presents well the basic anatomical facts to leucotomy

### Atlas of Epidemic Diseases

t II section I. Editor Dr Ernst Rodenwaldt delberg Sponsored by the Heidelberger Akademie Wissenschaften. Hamburg Falk. DM 57 50

ou the support of the Bureau of Medicine and of the U.S Navy has been discontinued, the volume of this work has begun to appear under nsorship of the Heidelberg Academy of Sciences go loose-leaf format is similar to that of the first [1] and the present section covers eight diseases— al dysentery in Africa; relapsing fever in Europe x in Europe rabies in Central Europe trachoma lm disease sleeping-sickness; and Chagas there is also a population map of the U.S.A The -the English version is still heavy going in places— more space than the maps but they remain no han notes. This gives a pointer to the major tual defect of the work Just as films are invaluable , but only as aids, in teaching, so maps—apart traight geographical maps—should be explanatory ts and not *pièces de résistance*

### es of the Skin

n ed. Oliver S Ormsby M.D., Rush professor of rmatology emeritus University of Illinois, and milton Montgomery M.D., M.S professor of derma ogy and syphilology University of Minnesota. London nry Kimpton 1954 Pp 1503 £8

ew edition of Ormsby and Montgomery is always ortant event. For many years this book has been the most authoritative works on dermatology in nglish language—an Osler of the dermatologists n it, the inquiring reader can find all the information eds, carefully tabulated and with comprehensive nces.

a moot point whether 1500 pages is not the limit of expansion; but in a work of reference such as this dliness is not such a disadvantage as in a textbook o in his senses would attempt to learn dermatology ding a work of this sort from cover to cover rmatological art can only be acquired by selective g in the light of clinical experience but even the experienced of dermatologists can advantageously o this book, overtly or secretly according to his hoping for guidance and often finding it when nted with a rarity or a difficult problem

ensive use in this edition has been made of other itative works on histopathology syphilology ogy, tropical diseases and the like and it also ns contributions by DeLamater Farber Kierland obitz. *Today multiple authorship is inevitable* n the whole desirable Dermatology is concerned so many aspects of life—social medicine, industrial ine toxicology psychiatry bacteriology, and cs—to mention only a few—that the days of rehensive monographic textbooks are passing

contents are as up to date as they can be in any large ok in this age of rapid progress. Amongst the recent ons are items on cat scratch disease incontinentia nti facial eosinophilic granuloma and self-healing liomata Ecthyma contagiosa may be the correct for orf as it occurs in sheep but is it appropriate to the o as it affects man? The section on tuberculosis con only a short reference to the use of isoniazid in lupus ris and states that it is ineffective in erythema induratum inion with which many would disagree There are many ent clinical illustrations both monochromatic and red There are also many clear photomicrographs with ptive matter on histopathology This is an ideal arrange helping the integration of clinical and pathological ht. This volume is, in fact two works in one a complete to clinical and histopathological dermatology

is sad to record that Dr Ormsby died last year the proofs of this book were being read This h edition is his monument and a worthy one

### Bedwetting

Portia Holman M.D. M.R.C.P. D.P.M London Delisle 1954 Pp 40 5s

A short clear, practical book on bedwetting is what every family doctor needs at some stage of his career and here it is From a large experience of children with this symptom Dr Holman is able to classify the types of case commonly seen to simplify diagnosis, and to assure the doctor who takes the trouble to differentiate between the types that there is a large group of bedwetters who will respond without consuming much of his time, to treatment which will put no undue tax on his skill.

### Liver Injury

*Transactions of the Twelfth Conference September 1953 Princeton N.J* Editor F W Hoffbauer, M.D associate professor of medicine University of Minnesota Hospitals. New York Josiah Macy jun. Foundation 1954 Pp 231 $4.25

The future policy of the Josiah Macy jun. Foundation is as stated by its medical director to restrict the conferences on any one subject to five. This volume is the twelfth and *last* of a series on liver injury, and a worthy companion to its predecessors The main subject was the rôle of the liver in the metabolism of the three major foodstuffs

Carbohydrate metabolism of the isolated perfused liver of rabbits and cats was discussed by Lundsgaard and a discussion followed on glycogen deposition in the placenta and the increased sensitivity of pregnant women to the diabetogenic action of corticotrophin and the adrenal corticoids In the section on fat metabolism, which dealt mainly with the rôle of co-enzyme A, Gurin presented the important results of his work on the synthesis of fatty acids from acetate by an in vitro system of water soluble enzymes extracted from pigeon or rat livers In the section on protein metabolism the emphasis rested on the effect of diet upon the composition of the liver cell and on the search for a suitable standard of reference for the quantitative studies.

### Prerequisites of Good Teaching

*And Other Essays* Dr Ernest Sachs, Research Associate Surgery and Medical History Yale University Hamden Connecticut: The Shoe String Press 1954 Pp 118 $2.50

In this humane and nicely printed little book, Dr Sachs presents some of his random thoughts as a teacher and practitioner of surgery In particular he has some interesting things to say about the value of well-chosen questions in the instruction of students. The hazards and responsibilities of our profession—such as the need to warn the family of the seriousness of a patient's condition or to comfort them when an operation has failed or the need to decide what to do when a case is diagnosed too late or whether to prolong life in a hopelessly ill patient—are considered wisely if not deeply and the generosity and integrity of the writer light up every page

### Physiology and Biochemistry of the Skin

Stephen Rothman M.D professor of dermatology University of Chicago Chicago University of Chicago Press. Cambridge: University Press. 1954 Pp 741 £7 0s 0d.

Dr Rothman's learned and comprehensive study of cutaneous physiology is a monumental work As cyto chemistry tissue-culture and the many other methods of studying the skin are likely to yield valuable results in the future this edition will probably be the first of several

The book begins by describing the mechanical properties of the skin and its electrical behaviour Other sections deal with absorption vascular reactions, sensory and secretory functions, heat regulation, the pH the lipid film keratinisation collagen and connective-tissue ground substance pigmentation, and hair growth. Obscure matters such as peroneal alopecia the higher iron-content of the hairs of red heads the differing pH of the skin of man and domestic animals, and many other fascinating subjects receive due attention Some of the photographs are excellent particularly those of nail fold capillaries catheterisation of apocrine glands cholinesterase in eccrine glands and cholinergic fibres experi mental miliaria, and club hair formation. The diagrams are all good

---

[1] *Lancet* 1953 i, 628

The book contains something to help the inquiring mind on all dermatological problems and on the way in which Man responds to his environment It will be perhaps of most value to the physiologist and biochemist, but every practising doctor should find much in it to stimulate him, and after reading it he may feel competent to discuss the Krebs cycle as glibly as he (or his barber) already discusses the hair cycle , while sulphydril groups and disulphide linkages will seem like ABC

---

**The Practice of Local Anæsthesia** (4th ed. London Sir Isaac Pitman 1954 Pp 275 25*s* ) —The purpose of this book is to give a relatively concise and practical picture of local anæsthesia to surgeons, general practitioners, and anæsthetists, studying for their diploma , and since it has reached its fourth edition Mr George Bankoff can fairly claim a good measure of success The first part deals with general principles, while the second and largest part gives a detailed account of the techniques for producing local analgesia throughout the body Unfortunately, though a thorough revision is mentioned in the preface, little reference is made to work later than 1940 This precludes any mention drug lignocaine, which for several years now has been lished in the forefront of local analgesics, and it may perhaps account for the author's outmoded view of anæstnesia

**Synopsis of Medicine** (10th ed Bristol John Wr Sons 1954 Pp 1253 35*s* ) —Sir Henry Tidy's mas of compression continues to summarise the facts of and instruct in common practices Probably not greatest poets can claim to be lifted so often or so from the shelves as " Tidy," and their advice is explicit

**Biology of Anopheles gambiæ Research in West Africa** (*World Health Organisation monograph no 9* M H. HOLSTEIN, Dr ès Sc Geneva World Organisation 1954 Pp 172 13*s* 6*d* ) —This is an edition of a useful monograph published two year French (see *Lancet*, 1952, ii, 1065) The text is sub the same, with the addition of one or two paragraphs to more recent work, and the bibliography has been from 388 to 410 references The translation is accur clear , but the English text seems to emphasise the liking for technical terms.

## VALVOTOMY KNIFE

THE search for the ideal knife for mitral valvotomy still goes on Much time has been spent on attempts to solve this difficult problem It has always appeared to me that something quite simple would be the answer, and I suggest that Brock's knife, in its simplicity, is the most suitable instrument

However, as the cutting edge of this knife is always facing the atrial and appendiceal walls, there is the great danger that during its insertion and removal damage might be inflicted Because of this danger I have developed a rotating mechanism (fig 1) to be used in conjunction with Brock's knife The cutting edge of the knife can be kept close against the finger during insertion (fig 2) and rotated into the cutting position (fig 3) the exact portion of the valve has been palpated anterolateral cut is then made When the knife has passed through 180° (fig 4), the posteromedial is cut with the same sawing action and without the hand On completion of these manœuvres the can be split further with the finger The knife and are then withdrawn with the cutting edge again finger A clamp can be applied to the appendage purse-string sutures can be tied slowly as the fing knife are withdrawn together

It is a pleasure to thank Mr J Hartwell, who m prototype The instrument can be obtained from M Chas F Thackray, of Park Street, Leeds, 1

# Mental Health and Public Health

RE was a time not so long ago when mental could be discussed only in terms of woolly lence A fine thing we all agreed, but how did one come by it? It would be nonsense end that we have since learnt how to produce bundance within a generation but at least ve some hypotheses, based on observation and nent which deserve to be tested Thus we eason to suppose that the newborn infant and ther (or her substitute) form a unit and that rmal development of the child depends on being kept together We also think that an le or over anxious or unloving mother may her child's development unfavourably, and rmore that she may herself be all or any of hings because her relations with her own parents unsatisfactory We recognise that no man is nd (for the mental health of all of us is bound th our experiences as members of a group), iat, while any of us may break down under too stress, like an ill used machine, yet, unlike a ne, most of us have the power to adapt ourselves ere stresses, and to a very wide range of them led we have some inner security and are given to make the adjustment Since we are born uble as the sparks fly upward, this last capacity cially valuable for our health of mind Besides worth remembering that if we are influenced ur surroundings our surroundings are also nced by us both are plastic

r the past century the public-health movement outstanding example of man's influence on his ndings—has measurably altered the physical of our people for the better, and no doubt indirectly prevented some mental ill health as But mental health has never been a definite in British public health campaigns and so of this we the pioneers are now some way d other countries in this respect For instance 142 Dr JEAN MACLENNAN and Miss MURIEL L describe how mental hygiene is taught in ouver and it is noteworthy how large a part well trained public-health nurses play in the mme In the United States mental health ing is now a widely accepted duty of public h departments Dr GERALD CAPLAN[1] reports for more than three years the department of nal and child health of the Harvard School of c Health has been successfully exploring the bilities of a team approach to the provision of services for the family, beginning early in the first pregnancy The team (consisting of lists in obstetrics pediatrics nutrition psychi social work and public health nursing) tries to er in the initial stages any physical or emotional s which might disturb family health and ity and to remedy them before they have done s harm CAPLAN[2] has had previous experience of this work as psychiatric director of the Lasker mental hygiene and child guidance centre of Hadassah, Jerusalem Here the problem of teaching was complicated by language difficulties and by the widely different standards of culture of mothers attending the centre yet group discussions kept on a simple emotional plane, dealt with all sorts of topics raised by the mothers themselves—fear of giving birth to monsters fear of the evil eye, fear of dying fear of having too big a baby sexual problems during pregnancy desire for abortion, fear of a second birth when the first was difficult worries about household management and about the other children, sudden aversions towards husband and family, and sudden swings of mood Apart from these discussions short talks were given in the course of which the mothers were warned how common it is to feel no love or warmth to the baby for a few days or weeks after the birth, and were assured that this coldness passes These simple measures it was found not only relieved the emotional tensions of the normal pregnant women but revealed those who were more deeply disturbed and needed individual treatment There are divisions of mental hygiene and psychiatry in the school of public health both at Yale University and at Johns Hopkins—where the programmes of teaching and field demonstration are extensive (Nothing comparable is to be found in any public health school in this country) In the Netherlands too the teaching of mental health, and the training of public health staff for this work is well developed Dr A QUERIDO who is both the chief of the public health section of the municipal health service of Amsterdam and professor of social medicine in Amsterdam University speaks of mental hygiene as an integral part of public health care[3]

These instances suffice to show how far other countries have advanced beyond us in the teaching of mental health There are however some stirrings of life in this field, even here Thus Prof ALAN MONCRIEFF urged as long ago as 1950 in his Dawson Williams lecture,[4] that maternity and child welfare centres should take up the duty of teaching mental hygiene and he pressed for it again in his Newsholme lectures[5] We have recently commented[6] on the report of a London County Council study group, set up by Dr J A SCOTT medical officer of health for the County of London. They made the same proposal and suggested how it might be done and their views were supported by a cogent plea from Dr HEDY SYMONDS[7] who gave examples of the types of family situation which such teaching might ease In Edinburgh (p 160) there is to be a campaign to educate the public in the true nature of mental illness and to encourage the recruitment of nurses But these seedling endeavours make but a small showing on the bareness of the land

The original public-health movement had to fight the inertia of the whole community, and those who now wish it to cover mental health meet it seems some degree of inertia within the service itself For this the curriculum for the diploma of public health is partly responsible So little attempt does it make to orient the future medical officer of health to this aspect of his duties that he is often less well informed about mental health than a recently trained health visitor Indeed, a British nurse engaged in public-health work, who attended one of the W.H O seminars on the subject, remarked ruefully that she did not know how she was going to get the mental-health point of view across to the doctor under whom she was working In saying this we do not, of course, imply that the training of health visitors in mental health is by any means perfect both their training and that of the future medical officers of health requires revision and reorientation if this work is to be done , and courses are also badly needed for those already engaged in this field Proposals for such instruction regularly encounter opposition from those who have matured in another tradition " what," these are inclined to ask, " can anyone tell us about the management of mental-health problems which we are not already doing on common-sense grounds ? " But it is also usual, as a course proceeds, for this resistance to melt the very common-sense of the participants leads them to accept the new approaches opened up for them Nevertheless, as Prof G KRAUS[8] has suggested, where resistance is strong it may be wise to begin by training a few people only—choosing those least at odds with the notions of psychiatry—and leaving them for a time to leaven the lump of their co-workers

Child Health and the State London 1953

[6] *Lancet* 1954 ii 1005
*Ibid* p 1010

" What is there to teach, anyway ? " is another frequent question, and a far-reaching one , and the tentative suggestions of the L C C study group hardly begin to touch on the answer Of course the first months and years of life are important , of course the mother can do much in those years to make or mar the emotional development of her child and his subsequent mental health , and of course the maternity and child-welfare centres should accept the responsibility for teaching her what to do and—equally important—what not to do But the causes of mental ill health do not all begin to operate at the birth of the child some begin much earlier Dr G R HARGREAVES,[8] whose paper we published recently, shares CAPLAN's view that mental-health teaching should begin in the antenatal clinic, in time to allay the fears and anxieties of the mother during her pregnancy Such fears, when disregarded, sometimes end in psychosis or severe neurosis which may demand months or years of treatment At an earlier stage, HARGREAVES says, the symptoms are still plastic, and simple measures may tip the balance towards adjustment and recovery Many fears of the pregnant woman are absurd and archaic, but they are none the less alarming on that account it does no good, and may do harm, to pooh-pooh them Many of her anxieties, on the other hand, are well grounded, centring on the change in human relations which the birth of a baby brings to every family Quite simple teaching at the antenatal clinic, as well as group discussions of the kind suggested by CAPLAN, can help the mother at this time , and even the obstetrician, as HARGREAVES suggests, should be able give such help, and be willing when necessary to the collaboration of a psychiatrist in bringing mother, whole and safe, through pregnancy, labour, and the puerperium Indeed, QUERIDO that the duty of the public-health service to pre mental ill health runs throughout the lives of one of us, and should properly embrace infants, preschool and school children, young peo work, university students, those in their working women at the menopause, and the aged, as those whose mental well-being is assailed by hazards—such as patients discharged from tal hospitals, people living in overcrowded unmarried mothers, those discharged from young delinquents, the disabled, and those from diseases (such as tuberculosis and ve disease) which affect their lives in the Much of the work done by our public already has some bearing on the mental hea many of these people the children's officer psychiatric social workers, and the probation are all aware of this side of their efforts W now needed is to make what is implicit outsp and to extend the principles of mental hygien every part of public-health work It is an task not only our slums but our mental ho are overcrowded, and more of us are now hampered by neurosis and other forms of ill health than by the diseases which sp lack of sanitation Our sickness has changed public needs rather than tradition should now the pattern of our public-health service

## Pulmonary Hypertension

PULMONARY hypertension is now a well rec disorder, but much remains to be discovered abo ætiology Usually it is a complication of car pulmonary disease, but occasionally it is found absence of either The normal pulmonary resistance is low, and the pulmonary-artery is less than the systemic, even in the presence siderable variations in pulmonary blood flow nary hypertension can result either from a increased pulmonary blood-flow (such as occ a large patent ductus arteriosus) or from an in the pulmonary vascular resistance So more than one mechanism operates in th patient, as in patent ductus arteriosus with na of the pulmonary arterioles In mitral stenosis tension in the lesser circulation may result eit an increase in pulmonary venous pressure the increased resistance at the mitral valve, or increase in arteriolar resistance Severe pul arterial hypertension is always due to red the pulmonary vascular bed at the pre cap arteriolar level The causes of this be obstructive (as in repeated pulmonary various forms of pulmonary arteritis, or cal or secondary to pulmonary fibrosis or emp

Problems in the elucidation of pulmonar tension centre mainly around the mechanis sible for reduction in the lumen of the arter for the organic changes which may also be It has been known for some years that acute can cause pulmonary vasoconstriction and pulmonary-artery pressure [1 2] Thus

iolar changes have also been shown by other
ers [10 11] The cause of such changes is unknown
s and EDWARDS [12 13] have found that the fœtal
of pulmonary arteriole (in which the lumen of the
l is less than the transverse diameter of the
l wall) may be present in the Eisenmenger
rome, and have suggested that the high arteriolar
tance so produced constitutes a protective mecha-
which prevents the lungs from being flooded with
l under high pressure in this and other congenital
ders In patent ductus arteriosus the pulmonary
y pressure may become so high that the shunt
ses or may cease entirely

the realm of acquired heart-disease mitral
osis is one of the most usual causes of pulmonary
rtension Increased arteriolar resistance is
mon, and has been shown to be due both to
nic narrowing [14 15] and to reversible or functional
owing [16 17] Narrowing is not confined to the
ioles it has been shown by angiocardiography
cour in the small muscular arteries [18] The cause of this arterial and arteriolar narrowing is unknown, possibly it is induced in some way by the elevated left auricular and pulmonary capillary pressures. Anoxia may be a factor, since oxygen inhalation has been shown to lower the resistance [19] WOOD [20] has found that in mitral stenosis with a very high pulmonary vascular resistance there is right ventricular insufficiency rather than pulmonary congestion Arteriolar constriction is now usually regarded as a protective mechanism which shields the pulmonary capillaries from the powerfully acting right ventricle [17 21] but this view has been challenged by DAVIES et al [22] These workers have shown that in mitral stenosis the total pulmonary vascular resistance can be reduced by hexamethonium bromide without producing pulmonary congestion or œdema, and they claim that attacks of pulmonary œdema are commoner in patients with an increased vascular resistance than in those without Unfortunately their data are not sufficiently complete to show conclusively that hexamethonium acts solely by dilating the pulmonary blood vessels through a reduction in arteriolar resistance, reduction in systemic as well as pulmonary resistance may play a part [23] While it seems likely that an extreme arteriolar resistance shields the pulmonary capillaries at the expense of the right ventricle, this may not always prevent pulmonary œdema nor is it necessarily beneficial

In recent years there have been many reports of pulmonary hypertension due to an increased arteriolar resistance in the absence of congenital or acquired heart-disease or of pulmonary disease In 1940 DE NAVASQUEZ et al [24] described cases of right ventricular hypertrophy of unknown ætiology in which the pulmonary arterioles were normal at necropsy DRESDALE et al [5] in 1951 reviewed "primary" or "essential' pulmonary hypertension which predominantly affects young people and is characterised by symptoms and signs of severe pulmonary hypertension due to a high arteriolar resistance without any cardiac or other pulmonary disease WOOD [21] drew attention to the occurrence in this disorder of tiredness, dyspnœa syncope, and even angina of effort and of a small pulse and cold extremities a giant a wave in the jugular venous pulse right ventricular hypertrophy, narrow duplication of the second heart sound with accentuation of the pulmonary element and sometimes pulmonary systolic or diastolic murmurs Cardioscopy shows enlargement of the right auricle, ventricle and pulmonary artery, with clear peripheral lung fields The electrocardiogram shows distinct right ventricular dominance The arterial-oxygen saturation is initially normal but may become slightly reduced as the disease progresses yet cyanosis, when present, is usually peripheral Recently CUTLER et al [25] have described seven patients with this disorder which they have designated the pulmonary vascular obstruction syn

drome All had extremely high pulmonary arteriolar resistances, and at necropsy in two of the cases the pulmonary arterial tree showed patchy atheroma, the large elastic branches having hyperplasia of the media with duplication of the elastic lamina and slight degenerative changes The muscular pulmonary arteries were the seat of pronounced subendothelial fibrosis, often occluding the lumen, many were obliterated by thrombi The capillaries and veins were normal GILMOUR and EVANS[20] described endarteritis fibrosa in the muscular pulmonary arteries in a case of primary pulmonary hypertension, and concluded that these changes might be secondary to the hypertension Necropsy studies in other series[24] have not always revealed any definite vascular abnormality, and DRESDALE et al[5] considered that the anatomical changes present in some cases might be secondary to neurogenic vasoconstriction Cor pulmonale due to multiple pulmonary emboli has been described,[27] but CUTLER et al[25] do not regard this as the cause in their cases They suggest that an extremely high arteriolar resistance in congenital heart-disease (particularly ventricular septal defect) may be due to a separate, possibly genetically determined, pulmonary vascular disorder WOOD[21] emphasises the rapid progression of primary pulmonary hypertension, but the condition of two of the patients described by CUTLER et al did not deteriorate for twenty to thirty years They mention the risk in such cases of sudden death, and remark that these patients tolerate any diagnostic procedure badly, one of their patients died suddenly during cardiac catheterisation

The organic arteriolar changes found in severe pulmonary hypertension, from any cause, have features in common the factors responsible for arteriolar constriction may also be similar Until this mechanism is known much will remain obscure, but studies with drugs which cause arteriolar dilatation may yield further important information Further examination of the bronchial circulation may also throw light on disordered function of the pulmonary vascular system[28] Meanwhile it is useful to remember that the clinical picture of severe pulmonary hypertension is remarkably constant, whatever the cause, and resembles that of the "essential" type, especially in patent ductus arteriosus where the flow may be reversed and the typical murmur absent, and in mitral stenosis where the diagnostic auscultatory signs may be negligible or absent as a result of the greatly reduced flow through the mitral valve Treatment of the pulmonary vascular obstruction syndrome is unsatisfactory, except in mitral stenosis where successful valvotomy may be followed by a fall in vascular resistance,[20] and in patients with a patent ductus which has been ligated before the shunt has ceased or reversed Accurate diagnosis, which is often possible only by cardiac catheterisation or angiocardiography is therefore essential For the rest, treatment with vasodilator drugs, such as tolazoline or methonium compounds,[5 21 22] may be worth trying

# The Fertility of British Women

THE fears so often expressed about the

of our population and the decline of our birth

led to the appointment of a Royal Commissio

Population[1] whose final paper, on the trend

pattern of fertility in Great Britain, appeared

week[2] Though "planning" is a word which

lost a little of its pristine savour, some intel

predictions must be made about the results of p

trends in fertility and family size if our

are to be anticipated and resolved To obtai

basic data, the commission asked Prof D V G

and Prof E GREBENIK to undertake a family

encompassing more than a million women in

United Kingdom Their report on this

conducted in 1946, has interest as much for

discussion of methods as for the results

This survey, supported by none of the legal

of a national census, relied entirely on the coöpera

of individual women, public relations were then

vital Press and B B C publicity was consid

and in the main helpful, though some papers

against "snooping" which was "entirely rep

to the British sanctity of the home which has b

been our national heritage" On the day,

tenth reference leaf was drawn from the alphab

ration-book file at every food office in Great B

From that sheet the names of all apparently m

or widowed women were extracted, and questi

were despatched to them by post These

who formed a representative 10% sample of

national total, were asked to report their m

status, the number and dates of birth of their chi

and their husband's occupation Thirteen thou

locally recruited enumerators called on them

to collect and check on their replies In all

inquiries a high response ratio is essential to suc

and for a voluntary inquiry of this type, the

reply was remarkable A personal letter from

chairman of the commission, emphasising the

ance and confidentiality of the inquiry, pro

a response from some of the more reluctant

contact could be made with women who existed

in the imagination of those who profited by

ration books, while in some sections of London

was little hope of finding women "at home"

accommodation address, even in the required

calls In the second week of the census came

announcement in the House of Commons

end of the supply of dried eggs and the cost

family census stirred up adverse comment, an

caused a sharp acceleration in the usual increase

non response rate which comes with deepening

and resistance Response-rates differed ac

to the region of the country, surprising

Northerners proved particularly docile,

worst response-rates were in the larger urb

where problems of contact were greatest C

tion depended, above all, on the interviewer,

best when he combined previous experience

subtlety of approach—as in the enumerato

2 The Trend and Pattern of Fertility in Great Britain on the Family Census of 1946 by D V GLASS and E G Part 1 Report Part 2 Tables H.M Station 1955 Pp 306 and 253 70s the pair

led to the sense of solidarity of the working s by pleading that he was only trying to earn onest fifteen coppers which were paid for each leted schedule Corrections were made for the differences between regions and population ties by duplicating or rejecting records at om so as to bring local response-rates into line the national average of 87 5%

me cross-checks between the results of the family s and national vital statistics convinced the ors that the sample obtained was in fact reason representative, and that conclusions could be y based on it The survey showed that between and 1925 the number of live births per woman ned by 62% from 5 8 to 2 2 More striking ps is the virtual elimination of the large family e late 19th century three fifths of all families sted of five or more children but in the 1920s families were of only one or two children childlessness had doubled in frequency Fertility s with age at marriage and with social class ough the professional classes, with their small lies do tend to marry late, late marriage does ully explain the rise in family size from 1 6 among ied employees and 1 97 among non manual -earners to 3 35 among industrial labourers Indeed, age at marriage and family size are related only in so far as they are both expressions of the complex of social attitudes which distinguish one class from another That these social attitudes are not fixed and immutable is shown by the changes in reproductive behaviour even within the same social grouping in the last fifty years, the wives of employers married in the '90s had just as large families as the wives of unskilled labourers married in 1920–24 Again not only have families become smaller but the space of years in which families have been completed has contracted, and the birth rate has fallen most notably in the period after the first ten years of marriage

Long range population predictions are at best an educated guess GLASS and GREBENIK are therefore cautious in their projection of future trends from past events, but they point out that ultimate family size which fell steadily up to 1930 and maintained an uneven stability thereafter now shows a slight upturn Because of the improving mortality experience and realisation from these data that family limitation is already widely practised in all social classes they feel reasonably confident that continuation of current fertility rates will achieve the desired effect of population stability

## CEREBRAL ARTERIAL DISEASE

ERE has long been uneasiness about the classification congenital defect of the change underlying rysms of the circle of Willis This concern was d most strongly by Glynn[1] who pointed out that e circle of Willis congenital defects were eighty as common as aneurysms Some additional factor sisted, must be involved in the formation of ysms. He showed that the defects were not in weak spots and did not bulge or break when after the vessels were overdistended at pressures about times the normal systolic pressure The fact that were far commoner in adults than in infants does xclude a congenital origin, since growth and rise ood pressure could make manifest minute funda l defects. In fact berry aneurysms are associated coarctation of the aorta and polycystic kidneys[2] ditions in which there are hypertension and other nital defects. Forster and Alpers[3] have recorded ase of a 13 week-old infant with unruptured ysm and polycystic kidneys This strongly suggests ngenital origin—a clear cut malformation of the possibly through the mechanism described by whereby the many small vessels present in the embryo fail to concentrate into the one main of the normal adult This is in keeping with the ation that abnormalities of the circle of Willis ore usual in patients with aneurysms than in those t If this is really the mechanism the congenital nality is the whole aneurysm not merely the ess in the wall hypertension enlarges and may o the persistent abnormal vessel but it is not y responsible for the formation of the aneurysm a minor defect Handler and Blumenthal[4] have ed inflammatory changes in the basilar artery and suggested that these are related to the formation of aneurysms[4] This does not accord readily with the usual picture of a clean break in the aneurysmal wall Moreover the basilar artery is not a usual site of aneurysm and no exciting causes have been found for this peculiarly local inflammatory reaction The well known mycotic aneurysms of infective endocarditis are clearly unrelated to the aneurysms which are the usual source of subarachnoid hæmorrhage The reaction seen by Handler and Blumenthal is probably secondary to local degenerative plaques

Current ideas on atheroma have been severely handled by Duguid and by Crawford who have shown the inadequacy of the hypothesis of simple lipoid imbibition and secondary medial changes from pressure Blumenthal et al[5] have taken up the question of localisation of atheromatous patches in the larger cerebral arteries Although the total quantity and distribution of atheroma in various arteries may vary enormously if present it occupies standard places and configurations; and Blumenthal and his colleagues have shown a correlation between tension on the wall and plaque formation They do not appear to have fixed the arteries they measured in a state of distension to the normal pressure Crawford and Levene[6] have shown the great difference this makes to the picture the apparent bulge of atheroma into the lumen is then replaced by a bulge into the media The problem of atheroma is thus being approached from two angles—the metabolic and the mechanical Blumenthal clearly regards arteriosclerosis as an adaptive response rather than a primary degeneration: the bulky local accumulations of fatty material would follow rather as aberrations of repair than as defects in normal intima and the prevention of atheroma would have two steps—the avoidance of strains in the arterial wall requiring repair, and the avoidance of lipoid accumulations in these areas of repair The two parts of this mechanism which are not necessarily related, fit the known correlations of atheroma with increased blood lipids and with prolonged arterial hypertension.

## THE RESTFULNESS OF CHANGE

> "Volumes are now written and spoken upon the effect of the mind about the body Much of it is true But I wish a little more was thought of the effect of the body on the mind"

IN setting down this perennially modern reflection, Florence Nightingale[1] was considering the havoc a sick body can play with mood and judgment Those who "think that 'with a little more self control' the sick might, if they choose 'dismiss painful thoughts' " fail entirely, she held, to realise what they are asking of the patient "Almost every step that crosses his room is painful to him, almost every thought that crosses his brain is painful to him, and if he can speak without being savage, and look without being unpleasant, he is exercising self control" It is therefore the business of his attendants to alleviate his depressed and irritable state by satisfying the "craving for variety in the starving eye"—giving him not merely a "judicious variety" of flowers, but a pleasant view, and pleasant things about him.

We do not give much thought to this principle in hospitals nowadays Flowers are certainly present, but there is little other attempt to provide variety hygiene, in fact, has ridden roughshod over psychology The patient in the public ward suffers less in this respect than the patient in the private ward for the patient in the public ward can at least refresh his eye with a variety of nurses, a variety of fellow patients, and a variety of nursing techniques as well This may not be quite what Miss Nightingale had in mind, but they are better than the blank wall set with glazed lavatory tiles which often confronts the patient in a private ward The craving for the return of day, she suggested, is often nothing but the desire for light, "the relief which a variety of objects before the eye affords to the sick mind" When these objects lack variety the mind gets no respite, and to this she attributed the depression so commonly seen in the chronic sick "subjected to a long monotony of objects about them" She might have added that the daily inspection of a blank tiled wall sometimes suffices, within a week or ten days, to convert a convinced optimist into a practising pessimist

Would she had thought that the need for variety (with a small "v") is sufficiently met by the broadcast programmes dispensed to hospital patients? It is doubtful, for, like so many of us, she seems to have been a "visual type," accounting sight the prince among the senses Does television perhaps supply the kind of nourishment the eyes of the sick crave? It is difficult to place a television screen so that all the patients in a ward can easily see it and there will always be some for whom the content of a given programme lacks appeal

Miss Nightingale proposed, as she so often did for other problems, a simple and practical solution The ward, whether public or private, is no place for a medley of agreeable knick-knacks, on the other hand its walls offer ample hanging space for pictures, and these can be changed The changes need not be made unduly often she pointed out that if you show a patient ten or twelve pictures in rapid succession you merely make him tired or feverish, "but hang one up opposite him, one on each successive day, or week, or month, and he will revel in the variety"

Some hospitals—but not many—have already had frames fixed to the walls into which pictures can be slipped, and they either keep a supply of good reproductions which are placed in these frames in rotation, or else they make use of the circulating library of pictures provided for hospitals by School Prints Ltd[2] This service was established about a year ago, and is steadily supporters

School Prints send a set of six pictures at a time, m on hardboard and varnished (but unglazed), so edged th have the appearance of being framed They are thu to collect little dust, and are in any case easily wiped o a damp cloth Each carries a small neat label giving th of the picture, the name and nationality of the artist, a dates Each set of pictures includes one showing p portrait or a scene with characters), two landscapes, tw river scenes, and one decorative subject, one at least o is by an old master, and the rest are by later or living At the end of four months a new set of six pictures and the original six are packed up and sent off to th hospital on the rota

Some hospitals—Orsett,[3] in Essex, for instanc had murals painted, which give gaiety and variety t wards Miss Nightingale, rightly or wrongly, that such refreshments to the mind act also on the "Little as we know," she wrote, "about the which we are affected by form, by colour and do know this, they have an actual physical effect of form and brilliancy of colour in the objects to patients are actual means of recovery" She capital observer, and her advice, even after a years' delay, is well worth taking

## DEFORMITIES OF THE CHEST WALL

CONGENITAL deformities of the anterior chest naturally into one of two groups—the pro the depressional The protrusional deformity is due to rib overgrowth When this is bilateral the protrudes, when unilateral the ribs are unusually nent at the costochondral junction Patients type of deformity have restricted chest expans movement of the diaphragm may also be affected deformity may be treated surgically either by osteal resection of the sternum, or by resection costal cartilages, after which regeneration is al occur in the normal position Lester[4] has descr cases in which patients underwent operations of this and he assesses the results as largely satisfactory

Depression of the chest, which is commoner, is associated with shortening of the central tendon diaphragm and backward curvature of the st Evans[5] has studied the cardiac changes asso this deformity Most of the patients have a murmur and an abnormal cardiac outline on ra associated with narrowing of the space between and thoracic vertebræ Lester has operated patients with sternal depression In infants the def may be relieved by excision of the xiphoid and costal cartilages In children and adults a more operation is necessary The 3rd–7th costal ca are resected, and a transverse wedge osteotomy across the 3rd sternal segment The xiphoid is and the body of the sternum elevated The stern be retained in position either by stainless steel passed behind it and tied to an anterior supp by using a section or rib as a strut[6] The results 90 operations are said to be functionally good patient died and 4 required reoperation In this Chin and Adler[7] have operated on 10 patien funnel sternum They suggest that operation sh advised for all children over the age of 6 months, adults with symptoms due to this deformity Th that the sternum can be freed from the diaphra after osteotomy can be retained in an over-co position without external fixation The costal ca are removed if they are deformed

any years must pass before the results of such ations can be assessed If the depression is really to shortness of the diaphragm, then the deformity recur as the fibres of this muscle find a new chment and if they fail to become reattached herniation may ensue In few patients are the symp s due to funnel sternum severe enough to demand ical relief although operative correction may nately be justified on cosmetic grounds alone

## ATTEMPTED SUICIDE—AND AFTER

atchelor and Napier[1] have followed up for a year fate of 200 patients who had been admitted to an rvation ward in an Edinburgh general hospital for mpted suicide They traced all but 1 and their ings should be valuable not only to psychiatrists to general practitioners Their series comprised men and 108 women the commonest diagnoses on ission were 'depressive state' (41 men 71 women) psychopathic state (25 men 17 women) epilepsy zophrenic and paranoid reaction organic reaction s, and mental defect contributed much smaller bers. The ages ranged from fifteen to over seventy the largest number for any decade was 48 (22 26 women) aged twenty to twenty nine though next three decades with 38 (17 men 21 women), 17 men, 14 women) and 37 (16 men, 21 women) well represented 106 patients (53%) were kept in general hospital for a week or less 69 (34 5%) for to two weeks, and 25 (12 5%) for longer Of this group three fifths were discharged home 6 (3 men men) died in the observation ward 3 from advanced se of the central nervous system, and 3 from respira or cardiovascular disease Of the remaining 194, (51 men 63 women) were discharged home 48 (21 , 27 women) were transferred as voluntary patients ental hospital and 7 (2 men, 5 women) were trans ed under certificate; 22 (13 men, 9 women) were sferred to a neurosis clinic or nursing home; and r disposals totalled 3

% of patients were discharged home compared 57% also in Hopkins's[2] series and 20% in Stengel's[3] helor and Napier point out that the majority were arged home after less than a fortnight in the observa ward but each case was thoroughly investigated and continued to attend under their care as outpatients believe that their rather free policy was fied by its results. During the year 4 of the patients mitted suicide and 3 of these had been in the mental ital the 4th suicide and 7 other patients who made er unsuccessful suicidal attempts belonged to the ically temperamentally unstable group for whom ave at present no effective treatment or suitable ision The Edinburgh workers consider that al hospital care is needed chiefly for attempted les with depressive schizophrenic, and paranoid oses and more often for those past middle age for young people automatically to send every pted suicide into a mental hospital is not only essary but wasteful of mental hospital beds But emphasise the serious suicidal risks accompanying epressions of late middle age and of old age, especially the depression has been initiated by the breakdown relationship characterised by intense possessive with resultant hostility towards the loved person g to severe guilt feelings At the close of the only 13 5% of the patients were in mental hospital; were at home and 59% were at work

cussing social reverberations, Batchelor and r agree with Stengel that in some instances attempted suicide may be in the nature of an appeal to family or friends to come to the rescue when the patient is at his wits end but they point out that some melancholics seem completely self absorbed They insist that the patient who has attempted suicide needs not only a chance to recover in a sheltered environment but help in fitting himself once more into his social setting The near relatives, too may need help; in many cases the disturbance to the family dies down quickly but in about 15% of cases the families were emotionally dis turbed for some months 3 relatives had to be treated psychiatrically and 1 woman tried to commit suicide seven months after her sister had done so

It is a pity that this excellent paper does not include data on social and family background or marital status which must surely have influenced Batchelor and Napier in their 'rather free policy' but no doubt they will further explore the lode they have opened up

## GENITO URINARY INFECTIONS WITH HÆMOPHILUS

MANY bacteriologists will learn with surprise of the claim by Gardner and Dukes[1] to have isolated a new bacterium which they regard as the cause of most cases of non-specific vaginitis. They state that a previously unidentified and unclassified hæmophilus has been isolated as the predominant or only organism from 81 of 91 such infections From a clinical study of the cases in 62 of which the hæmophilus was the only organism present Gardner and Dukes report as evidence of a specific disease-entity that the vaginal discharge is grey thin homogeneous offensive in smell and less acid than normal vaginal secretion and that itching and irritation are seldom prominent They reproduced the disease in volunteers by direct inoculation with infected vaginal material and pure cultures of the hæmophilus Direct films of the discharge showed abundant, short, pleo morphic, gram negative rods which could be cultured with some difficulty in an atmosphere of carbon dioxide and only on 'proteose peptone No 3 agar' containing 10% sheep blood The organism was sensitive to the tetracycline group of antibiotics and to sulphonamides Administration of these drugs by mouth or into the vagina eradicated most of the infections. A complete account is to be published[2] and most will prefer to reserve judgment about the novelty and the causal rôle of the hæmophilus until the full report has appeared

Meanwhile, the brief description of the organism inevitably recalls a rather similar account by Leopold[3] who reported the frequent isolation from urine and cervical swabs by strikingly similar cultural methods of a hæmophilus which was hæmolytic In males the presence of the organism in the urine was associated with mild prostatitis with or without urethritis; in women there was an association with cervicitis. Leopold found the organism in the urines of 53 of 905 unselected men and of 2 of 18 men with a previous history of non specific urethritis in 16 of 58 cervical swabs; and in the urines of 4 of 9 men whose wives had positive cervical cultures

Few bacteriologists nowadays expect to discover a hitherto undescribed bacterium as the cause of an infec tion But possibly they have too readily abandoned this type of search to the virologists There is some danger of discovering only the bacteria that are expected in any disease process because the methods of culture applied are those best designed to isolate such organisms and to discourage as many others as possible. Whatever may be the final judgment of the new claims there would seem to be no insuperable difficulty in the way of attempting to repeat the observations of Gardner and Dukes

# THE WORK OF A MENTAL-HYGIENE DIVISION IN A PUBLIC-HEALTH DEPARTMENT

JEAN M MACLENNAN
M D Edin, D P.H.
HEALTH UNIT DIRECTOR, VANCOUVER, FORMERLY SENIOR ASSISTANT MEDICAL OFFICER OF HEALTH, HENDON

MURIEL E SMALL
R N, B N McGill
ASSISTANT UNIT SUPERVISOR, VANCOUVER

THE view is now widely accepted that mental hygiene is the proper concern of a public health department The prevention of all forms of preventable illness and disability is the natural aim of a truly comprehensive public health service Within the scope of such a comprehensive service come many forms of psychological and emotional disorder The methods of prevention of psychiatric disabilities are various, for they are not yet as well tried and standardised as those used in the prophylaxis of infectious diseases, for example So a description of the functioning of one mental-hygiene division within a public health department may be attempted for reasons of comparison and review

The public health worker is not inclined to invade the already well-cultivated field of psychiatric treatment He would be content to leave therapy with those whose particular interest it is and to concentrate his own efforts upon his own territory in "the recognition and eradication of factors in the community which are harmful to the healthy psychological development of individuals" rather than in "the treatment of the results of those factors"[1] However, psychiatric treatment of children can be very time consuming, and the sooner emotional difficulties and unhealthy attitudes to other people are recognised the more easily they are corrected The natural division seems to be not between therapeutic and preventive services but between clinics which offer intensive therapy and those which offer guidance and "superficial" therapy Furthermore, in staff education in the principles of mental hygiene, case studies under supervision are a sine qua non thus with a basically preventive orientation the public health worker still finds himself doing a fair amount of treatment

### THE METROPOLITAN HEALTH DEPARTMENT

In Vancouver, the mental hygiene division of the public health department was set up in 1939 An integral part of the health department, it functions like an 'enzyme system," permeating the work of other divisions within the department and through them the health of the community as a whole Its activities can be more pervasive than those of a child guidance clinic which operates within an education department and is—administratively as well as in orientation—more confined

The health department is set up on a metropolitan basis to include the spreading urban area of Greater Vancouver The Metropolitan Health Committee, which directs the department is composed of elected representatives from the City of Vancouver and five surrounding municipalities, together with the university area and another smaller area of the adjoining part of the province of British Columbia The population served was estimated, in 1953, at 522,030 The population of the City of Vancouver itself was 390,325 for the same year The whole of this urban and suburban area exceeds over 248 square miles

The work of the health department is centralised in Hall, from which many of the services operate The personal health services and sanitary inspec are directed peripherally from seven "health four of these being within the City of Vancouver other three covering surrounding areas

The total staff of the health department compr professional and lay officials, including 13 full time and time medical officers, 114 public health nurses, 36 inspectors, 19 dentists, 2 psychiatric social workers, logists, 2 nutritionists, and 2 audiometrists, all general direction of the Senior Medical Health Officer

The work of the medical health officers and of the health nurses is diverse, covering school health and kindergartens, child-welfare work and child centres, immunisation and communicable disease (including tuberculosis and venereal disease, in tion with the provincial departments of tubercul venereal disease control) Mental hygiene work out in relationship to these other activities and an increasing amount of time and attention staff meetings are held both in the health units and City Hall

Each health unit is led by a medical health who is the "unit director," and by a senior public nurse, who is the unit supervisor In the large there are also assistant unit supervisors The of public health nurses attached to each unit from 4 to 17 according to the population and each area

### OTHER AGENCIES

The staff of the metropolitan health department school services to the "public schools" (i e, are publicly provided and administered by the of school trustees of the City of Vancouver, and other municipalities of the metropolitan area) mately half the time of the unit directors and other full-time medical officers and of the public nurses is devoted to school work Certain "non schools" are also provided with health service are essentially church schools

The provincial government of British Colum the major health authority, has its divisions of culosis control, venereal-disease control, child guidance, and others in its health de the metropolitan health staff work in close with these The child guidance clinic of the health department has its headquarters in It is more concerned with treatment than is the hygiene division of the local health department, has prevention as its primary objective It understood therefore that these two agencies attract a rather different case-load, and that ca be referred from the metropolitan mental hygiene to the provincial child guidance clinic The of demarcation between prevention and treatme ever, has been somewhat erased, and the local department has assumed perforce a minor "treatment"

The work of the metropolitan health staff assisted by the local medical profession practice and by the hospitals The Health Ce Children at the Vancouver General Hospital larly valuable to the children of the city, pro wide range of outpatient and inpatient faciliti director of the mental hygiene division is an psychiatrist on the staff of the Health Centre for and a director of one of the health units is at its staff as a pædiatrician in the outpatient dep A senior member of the staff of the Health Ce as consultant in cardiology to the metropolit department A public health nurse of the men staff is employed full time in the health ce "liaison" public-health nurse The local health ment is thus linked clinically with the teaching s pædiatric functions and has a small share in raining of medical and nursing students in child

---

[1] W H O Technical Report no 9 1950

e metropolitan health department provides instruc to students in various faculties of the University ritish Columbia—including medicine nursing and economics Its staff works closely with the rian Order of Nurses (domiciliary nursing service) Children's Aid Society (child life protection) the social service department (relief of indigents) the pled Children's registry the B C Tuberculosis ety, and many other voluntary and municipal nisations.

### THE MENTAL HYGIENE DIVISION

e staff of the mental hygiene division engaged le-time in this work comprises a director and assistant tor who are specialists in psychiatry two psychiatric l workers (a man and a woman, the latter being a qualified public-health nurse) and two psycholo

The director is also director of the school health ce for the city of Vancouver He and his assistant tor conduct the mental hygiene clinics which operate he various health units The psychiatric social ers are engaged mainly in reinforcing and guiding work of the public health nurses in the schools and s they take a prominent part in staff education[2] psychiatric social workers also carry out individual work on a limited number of cases

o psychologists work very closely with the psychia in the mental hygiene clinic, assisting in the osis carrying out psychometric examinations and ding therapy The psychologists also coöperate the medical officers and public health nurses in in selected child health centres seeing particular referred to them and reviewing the progress of rently normal healthy babies. These members of ental hygiene team work in the closest relationship the public-health nurses medical officers, the unit tors and the unit supervisors The medical officers he public health nurses bring forward the problems he environmental and social data while the staff e mental hygiene division coöperate in furnishing gnosis and recommendations which are carried out by the staff members concerned Thus from the al hygiene division the stream of thought and y and action flows out via the units into the schools ho homes where the children of the rising generation eing educated and nurtured Directly and indirectly school staffs are affected Parent associations are g increasingly into this community of thought gh formal lectures, discussion groups or round conferences other interested bodies are reached church groups racial associations university ences, and others

the periphery the public health nurse and medical go about their daily routine in schools child health s and clinics The work of the public health nurse akes her into the homes of the people through to tuberculous patients young infants expectant rs and others in need of her services Daily ts with teachers and pupils in the schools with rs in the child health centres and with families in homes, keep the public health nurses in constant with the problems and needs of their patients f the referrals to the mental hygiene clinic come e public health nurse or the medical officer they me from the teacher or from the parent to the health nurse in the first place More and more re being referred by private medical practitioners casionally cases are referred by other social

### THE MENTAL HYGIENE CLINIC

The mental hygiene clinic is the main focus of all this activity It is primarily a clinical consultation which culminates in diagnosis and recommendations for treatment but its usefulness is not limited to the needs of the individual case Thus it has a most important educational function particularly for the new recruits to the public health nursing and medical services Where a school child is concerned its impact is felt in the schools for the child's teacher and school principal are usually present when the case is presented at the conference which follows the clinic session

The clinic is held as a rule once a week in each of the health units One psychiatrist and one psychologist are always present and the psychiatric social worker may be present for a varying amount of time Usually 3 cases are dealt with at each session. The consultations and examinations are held in the morning while the case-conferences are convened in the afternoon Those seen are usually school children mainly aged 6 10 In 1953 254 new cases were seen

In the preparation of the case several visits have to be made to the home by the public health nurse, who then prepares a detailed case-history which includes an extensive family history as well as an account of the relationships of the child at home and in school Wherever possible she talks to both parents and in some cases to other relatives living in the home

At an early stage the child is referred to the medical officer if he has not recently seen him The unit director may contact the private practitioner where necessary and the public health nurse is also in touch with other social agencies which may have been concerned with the family (A useful organisation for this purpose is the Social Service Index where social agencies including our own register the names of persons who have applied for advice or assistance) The school authorities are also requested to furnish their report and this is made out in detail by the child's teacher covering academic achievement and social adjustment as well as the results of any intelligence tests which have been given at the school

At the clinic the child and one or both parents are seen by the psychiatrist who includes a full physical examination of the child in his evaluation of the case. Thereafter the child and parents are interviewed separately by the psychiatrist While the parents are consulting with the psychiatrist the child goes to the psychologist for examination and observation.

The relevant findings from these examinations are presented along with the other material data at the case-conference, which is held in the afternoon It is usually possible to indicate the problem in general terms without divulging personal matters which are best left as confidential details on the file

In addition to the staff of the clinic there are present the public health nurse the unit director the unit supervisor or assistant unit supervisor and also any of the following who are concerned in the case—class teacher school principal social worker of any other social agency which may be involved and also occasionally students in postgraduate nursing courses The problem is unfolded usually by the public health nurse or—if the problem has arisen initially in the school situation—the child's teacher and the school principal The psychiatrist as chairman calls on the persons who can contribute to the discussion The psychologist's account is always important In some cases a good deal of the background is known only to the family doctor who is invited to the conference but is rarely able to attend In such cases his report will have been submitted to the unit director The conference may occupy thirty minutes or up to an hour or more the psychiatrist coördinating the discussion and bringing out the main points in diagnosis and recommendations for further action. These are set out concisely but in some detail in the written report which is transmitted by the psychiatrist to the unit director after the conference A copy of this report is sent to all the agencies who may have an interest in the case—e.g., the school or kindergarten, the family doctor the school board and various social welfare agencies

### THE PUBLIC HEALTH NURSE

In the whole mental-hygiene programme, the public-health nurse is the key figure If the mental-hygiene division is a sort of enzyme system, then in order to get the enzymes (or mental-health principles) working actively to bring about change in the classroom and the home, the nurse must take them there Similarly, if the division is to continue to function it is the nurse who must be the case finder, bringing in fresh material for the triple purpose of education, prevention, and therapy Indeed, the main efforts of the whole division are directed towards equipping the nurse more fully for her task, and guiding and sustaining her as she carries it out

1 The public-health nurse is ideally situated to act as a potent force for mental health *in the community*, first because she is there, and secondly because she has in most cases no hurdle to take to be accepted as a "helping person"—she has been that from way back She knows the family in their own setting, and she is aware (or soon becomes so) of their limitations, their difficulties, their weaknesses, and their strengths To translate principles into practice in all sorts of varied situations is her traditional function If, then, she herself is imbued with mental-health principles, equipped with techniques of interviewing, and has a sound knowledge of the dynamics of development and behaviour who can more persuasively teach, guide, and support the parents of the growing generation?

2 *In the schools*, too, where part of her every day is spent, she can help the teachers to understand Johnny's behaviour in terms of his needs, and assist them in attempting to meet these She can make them aware of underlying causes in his background, and thus enable them to deal more understandingly and effectively with him

3 In her work *in the child health centres* she puts the same principles and the same equipment into action In her individual conferences with the mothers she has a unique opportunity to teach the known facts of normal growth and development, not in a remote academic way, but focused on this particular child as he is now For "visual aids" she needs little more than the baby himself It is in this setting, too, that she learns to detect unwholesome attitudes that may lead to later difficulties in the parent child relationship This has been termed "anticipatory guidance," and our attempts to introduce this concept into our baby centres have already been described[3]

4 Mental hygiene is not a tool to be applied to special cases but a way of working in all situations where one deals with people Some graphic illustrations of this have been given *in the field of tuberculosis*

A young married man, father of a small child, had a case history that read like the dossier of an incorrigible All workers had found him hostile and uncoöperative, and he had built up a tremendous hostility towards all agencies, institutions, and workers He refused to carry out any of the procedures outlined for him, or to attend his X ray appointments A new nurse fell heir to him and having read her predecessors reports, decided to seek help before making her first visit She discussed the case with the psychiatric social worker, a member of the mental hygiene division They talked about the possible reasons for this man feeling as he did, and the need to begin with an unconditional acceptance of his attitude, and complete absence of any criticism or attempt at direction The nurse visited, introduced herself, and let him talk—which he did at great length, venting his frustrations, his resentments his humiliations She resisted any temptation to argue, defend, cajole, or coerce At the close of the interview the patient was speaking quietly and with self respect, and ended by asking the nurse to make a ointment for him, leaving the way open for further

The emotional balance of the tuberculosis is almost always affected *to a greater or less* The nurse who realises this, accepts it and h courage and vision to postpone her immediate and apply her knowledge of human behaviour, do more effective work In this field all the knowle skill acquired through her mental hygiene work clinic and in staff education can be put into practic

5 When a case is being referred to clinic her much more formal, time consuming, and ex *The preparation of a case for referral*, and *the su follow-up*, when these are well and truly done, all that a nurse has in the way of observation, know skill, and patience

(*a*) Children are often referred to her by the It may be that a child is not working to capacity, dreaming and withdrawn, or is over aggressive and seeking The teacher discusses the situation with the and pooling their knowledge of the child, they talk of handling it The nurse makes a home visit and after discussion with the principal and teacher it may be to offer the parents the services of the clinic. It wo tedious to dwell at length on the factors basic to this d but briefly they are the nurse's need for further gu the parents' recognition of the problem, their desire fo ability to benefit from help However, this is more ideal, and sometimes cases are brought in where the are obviously a lost cause and plans must be made to help child without counting too much on them. In othe there are some cases—as there are in all big cities—wh prognosis for building family strengths is poor, and must be on therapy for the child

Either before or after the decision to refer the case to the nurse makes a number of home visits during whi obtains the information necessary to write up a fairly hensive social history Writing the history is often re as a tiresome chore, but the nurses have found that the views incidental to this, and the putting together of history itself, clarify the whole problem, and that by the the case comes to clinic both she and the parents have better idea of just where they need the psychiatrist The history varies in length, depending to some extent complexity of the problem and the individual the nurse A social history guide has been drawn up mental-hygiene division to help the nurse in gathering and in constructing the history Help may always be from the psychiatric social worker and the nursing

The nurse takes an active part in the case presenting the case, summarising the details of the personal relationship she has made with the family, and her reasons for bringing the case in Everyone else in, and at the end of the conference the diagnosis is made, and a plan of action agreed upon After whole thing is summarised in the psychiatrist's report, is filed with the history, together with any other matter, such as reports from another agency, and fr child's doctor, and the results of psychometric tests.

(*b*) Unless otherwise decided at the conference, the fo of the case is in the hands of the nurse Occasiona psychiatric social worker may be asked to work wi family on a case work basis, or the case may be han to another agency, for example, the child guidance cl Children's Aid Society, or the Family Welfare Burea great majority of cases, however, it is the nurse wh on, continuing to visit the home regularly, and se interpret and help implement the clinic's recomme both there and in the school This is sometimes on long term basis, continuing throughout the child's sc with progress notes written periodically and reass of the case in clinic as indicated If the family mov child is transferred to another school, the history is to the nurse who takes over

There is a great variation in case loads, of course, in the amount of time and effort spent on the individu and on the work as a whole In addition to all the variables (such as the severity of the problem the re ness of the parents, and the stability of the communit is the temperament and interest of the nurses Som great natural facility for this work, others find it and show more or less resistance, generally due to confidence in their ability to tackle this kind of

---

C H, Hall, B E, Hunter, T G *Public Health Nursing*, 1952 ro interested and with the increasing emphasis on this o field, both in preparation and in in service training has been over the years an increasing awareness, ability ureness shown in the nurse s work. For evidence of this has only to glance through the old files and compare the hy history and sparse follow up work of ten years ago those of today One cannot help but be struck by the th in understanding the sharpening of observation and ncreased competence of action, or in some cases the wise holding of action

his outline of the rôle of the public health nurse in mental hygiene work of this agency would not be plete without some reference to *group discussions* more or less informal but regular ' get together few people for the purpose of learning by discussion oing found effective in many fields Arranging discussion is not yet an established part of the lc health nurses' rôle, but the few attempts that been made are very promising Three of our nurses undertaken to ' lead " such parent groups with encouraging response We do not refer here to s to mothers or other groups, but a different freer e living and meaningful process in which the group f is the teacher The nurses and the parents who taken part in these have attested to the real and ng change that takes place in such a setting

f course the pitfalls on the nurse's path as she tries pread the knowledge of the normal and help to ent and correct the deviations from the normal obvious But through the mental hygiene clinic, the lar conferences with the psychiatric social worker or psychologist as her work progresses, and through her experience, the nurse becomes aware of her own ations and those of her agency and learns to work uctively within them. Some there are indeed who o so much of the dangers that they are blind to the ibilities But no-one can deny that mental health blic health and what public-health measure has not with reactionary resistance ? To safeguard against e dangers is one of the functions of the mental ene division

### SUMMARY

n account is given of the work of a mental hygiene ion in a public health department The organisation he metropolitan health department is described. elationships with other agencies are shown The position of the mental hygiene division is briefly hed and the influence of its mental hygiene clinic dicated Examples are given of the ways in which ublic-health nurse exercises her functions in mental ene work (1) in the community (2) in the schools, n child health centres, (4) in tuberculosis control in the mental hygiene clinic and (6) in group ssions

## BACTERIAL GENETICS

NETICS have an increasing part in the study of riological problems and in order to outline the uses techniques of the subject a colloquium was held in ion on Dec. 14–17 by a group of interested bacteriolo While the range of the discussion was intentionally a medical bacteriologist may have thought that a oportionate amount of time was spent in reviewing enetics of bacteriophage and of *Escherichia coli K 12* his can be justified by the fact these organisms are most susceptible to detailed analysis.

ening the colloquium B A D STOCKER gave an rable review of bacterial transformation and trans on by phage while W HAYES did the same for the ics of *Esch coli K 12* (Unfortunately many of the speakers did not maintain the same standard of ity This was partly because some participants presented new material instead of discussing principles such contributions tended to break the flow of the meeting and the informal air desirable in colloquia was lost ) Discussing the papers by Stocker and Hayes J L JINKS spoke of the exclusion factor which he believes to be an essential part of the mechanism of recombination in *Esch coli K12*

A discussion on population changes was opened by CHARLOTTE AUERBACH who emphasised that workers were sometimes not careful enough in their use of words for instance mutation ' was used to mean both the act of producing a mutant and the mutant itself She also pointed out the dangers in interpreting experiments in which selection of a mutant is involved D A MITCHISON described some of the mechanisms which may bring about large-scale changes in cultures referring mainly to the antibiotics. J YUDKIN sought to explain some of these changes on clonal variation—a hypothesis that would require revision of some of our ideas of inheritance of bacterial characters

The genetics of bacteriophage was next discussed In this field the fact that the result of crosses can be analysed is offset by our lack of knowledge of how the phages are reproduced at present no hypothesis of phage replication adequately fits all the known facts However ELINOR MCCLOY and NEVILLE SYMONDS described the main experimental facts in this field while W HAYES discussed the inheritance of prophage Other viruses were rather neglected but F FULTON did give a satisfying account of the recombination between influenza strains, and he suggested that the virulence of these strains was best attributed to an inherited pattern rather than to any single character

The final session was devoted to some of the applications of bacterial genetics, including its possible uses in the study of virulence T W BURROWS described the importance of growth factors in *Pasteurella pestis* strains while L F HEWITT outlined the rôle of phages in the toxogenicity of diphtheria D ROWLEY put forward a scheme (still in the experimental stage) for analysing the mouse virulence of *Esch coli* strains

The organisers are to be congratulated on their attempt to introduce the *study of genetics to a wider range* of workers.

---

## CEREBRAL PALSY

AT the national congress of the Societa Italiana di Ginnastica Medica held in Milan on Dec 6–8 Dr A COLLI GRISONI (Milan) pointed out that there had been a distinct change in the approach to the infantile cerebral palsies Formerly regarded as osteomuscular states, only partly amenable to static forms of treatment, they were rapidly becoming recognised as neurophysiological conditions in the developing child, calling for a dynamic approach Defective development should be evaluated from both physical and mental angles, in order to give a prognosis of a child s educability Her fundamental principles of treatment could be grouped under three heads—physiotherapy occupational therapy and speech therapy—and suitable personnel were about to be trained in Italy for this work Trainees with a vocation must be selected and specially trained in precise techniques of management She felt that babies are best treated at home children between 3 and 5 years at special day centres attached to hospitals and older children at schools for handicapped children She emphasised the importance of instructing parents in day to-day care of their children, and remarked that even children barred by mental deficiency from ordinary education can be helped to some extent Spastic children she said must first acquire complete relaxation ; then passive movements must be applied later passive active movements must be carried out ; and lastly, active movements

There was much to be done in the field of the infantile cerebral palsies, and neurologically based research should be encouraged

Dr L Massimo (Genoa) read, in translation, the commentary to an English film, previously shown in London This film, entitled *The Rôle of Mental Function in Physical Activity*, was prepared in the cerebral palsy unit at Queen Mary's Hospital for Children, Carshalton, and the associated parents' advice clinic The commentary pointed out that cerebral palsies may occur in mentally normal and in mentally deficient subjects, and that prognoses of ultimate compensation for these non-progressive motor disorders rest on evaluation of the patient's mental function

The film first illustrated the rôle of mental function in ordinary everyday activities of intelligent adults who, having been born without arms, were effectively compensating for their missing limbs The first, a mother of seven children, was shown doing housework and caring for her youngest child, the second, a young man, was shown at work The film then illustrated the development of mental function in normal babies, and showed the defective development of children with abnormalities of brain function Four defective babies were shown during clinical testing for primary abnormalities of mental and motor function. The tests revealed that two of the babies had no motor disorder, and two had both mental and motor limitations These four babies were shown stages of development, and the correctness of the thus demonstrated

The commentary emphasised the need for plann pensatory activity for children with primary motor and demonstrated the results of appropriate pl palsied children shown at play and in school Those of intelligence showed achievements, within their motor appropriate to their ages, and those with mental def failed in this respect Finally, two brothers were normal and one with cerebral palsy The boy with palsy showed activity which closely resembled that brother He had been competently helped from an to use his defective motor function skilfully for expr lively intelligence

The trend of the papers read and the films this congress was towards a new approach to the cerebral palsies—an approach based on neuro logical study of infant development, recognition of abnormalities, and practical application of principles in techniques of diagnosis and of of children with brain deficiencies

Mrs Eirene Collis, C.P T, of the cerebral palsy unit Mary's Hospital for Children, Carshalton, was awar the Italian Republic the *stella della solidarietà italia* services to the children of Italy

# Public Health

## Coloured Food

The Food Standards Committee has adopted a recommendation by its preservatives subcommittee[1] that the Public Health (Preservatives, &c, in Food) Regulations, 1925–53, should be amended so as to permit the inclusion in foods of specified colours only

The subcommittee, whose chairman is Sir Charles Dodds, F R C P, F R S, remarks that the practice of colouring food is by no means new

Pliny the elder, for instance, referred to the colouring of wine But it is only in the past hundred years or so that this practice has been open to possible objection About 1850 the "coal tar" dyes were discovered, and these have now largely replaced the natural colours previously used

In 1924 a departmental committee, appointed by the Minister of Health, recommended that the use of only specified colouring matters, regarded as non injurious to health, should be allowed But the Government of the day decided on a different approach, and under the 1925 regulations the inclusion in food of certain colours then known to be harmful was prohibited These were antimony, arsenic, cadmium, chromium, copper, lead mercury, and zinc, gamboge (a vegetable colouring matter), and five "coal tar" colours (picric acid, victoria yellow, aurine, manchester yellow, and aurantia)

The present position is that the Food and Drugs (Milk, Dairies and Artificial Cream) Act, 1950, prohibits the addition of colouring matter to milk, but otherwise any colours not specifically prohibited by the Public Health (Preservatives, &c in Food) Regulations, 1925–53, may be used in foods, provided that such use does not contravene the provisions of sections 1 and 3 of the Food and Drugs Act, 1938

The subcommittee observes that evidence has been accumulating which indicates that "coal-tar" colours other than the five already prohibited may be a hazard to health in laboratory animals some have proved carcinogenic

Without the addition of colour, says the subcommittee, many foods would have a drab unattractive appearance If, therefore, there is enough evidence that the colours used have no deleterious effect on health, it sees no objection to their being used to replace natural colour l processing, to standardise appearance, or simply a food more attractive But the report suggests that the addition of colour to raw meat, game, po fish, fruit, and vegetables should be prohibited (to best of its knowledge such additions are not being in this country)

The report ends with a list of colours which subcommittee suggests, should be approved for in food

Representations on the subcommittee's recommendations be submitted, up till March 31, to the Joint Secretary Subcommittee, Ministry of Food, Great Westminster Horseferry Road London, S W 1

## Fish and Chip Shops

In his report for 1953, Dr T R Roberton, officer of health for Bootle, describes how his de has been improving the standard of hygiene in chip shops in the borough Generally the shops well maintained, but one possible source of it is certainly not one that is confined to Bootle) improvised shed at the rear of some premises, wh used for storing, cleaning, and peeling the potat which was often an unsuitable place for the job report also refers to the wrapping of fish and ch "an inadequate sheet of grease-proof paper" and newspaper "the source of which was unknown" prietors were recommended to wrap the food in a suitable paper bag and to use "an external wr from an approved source"

## Geography of General Practices

Middlesbrough's health department lately made survey to find out the extent to which the local doctors' practices overlapped geographically report for 1953, Dr E C Downer, medical of health for Middlesbrough, tells how six street selected from different parts of the town, only which some member of the department ha be visiting officially were included in the inquir one street, 18 families were attended by 17 d doctors, in another, 25 families were attended doctors Each street surveyed had 10 or more covering from 12 to 26 families "From this it seen," Dr Downer comments, "that in times of spread illness or epidemics the general practit the town have to motor all over the town to their patients An enormous amount of time be spent by doctors at the wheel rather than bedside, and it is impossible to attach the health visitor as closely to the doctors as one w He suggests that, in the interests of economy, six doctors working in some form of group should be responsible for a large housing e of housing estates,' and that the choice of ors should be limited to those within this group ice

## Before Our Time

# MEDICAL MISSION 1855

M E S LAWS

O.B.E., M.C., F.R.Hist.S

FROM the medical point of view the Crimean War is best remembered for the virtual collapse of the British military administrative system the terrible casualties of Lord Raglan's force from cholera exposure and semi starvation and the failure to provide adequate hospital accommodation staff or equipment Under pressure of public opinion the Government made strenuous efforts to remedy these shortcomings and by early in 1855 there was promise of general improvement But it is not generally known that at this time when our own medical resources were under great strain to provide more doctors *for the army in the Crimea we also made a considerable* and successful effort to help our Turkish ally

Early in 1855 General Cannon who was head of a British military mission with Omar Pasha's army on the Danube reported that the Turkish troops had practically no medical organisation and were losing many men because of this He begged that a British medical staff *should be dispatched as soon as possible* with essential equipment to organise hospital facilities At that time the Government was still recruiting doctors for Lord Raglan's army and was also committed to finding doctors for his Turkish division of 20,000 men and an irregular cavalry corps of 4000 men which were being taken into British pay and service The authorities in London might well have declined to respond to General Cannon's plea and it is to their credit that they accepted this further task

It was decided that the medical mission to Omar Pasha's army should consist of an inspector general of hospitals a deputy inspector general four surgeons (1st class) fifteen surgeons (2nd class) four dispensers twelve dressers a storekeeper and a clerk All except two surgeons and one dresser were British but all were given Turkish military rank, varying from major general to lieutenant As few of the doctors had had any previous military experience it was perhaps inevitable that insufficient stress was laid on the need for physical fitness, and some of those who volunteered proved unable to stand the hardships involved Two surgeons died and the inspector general (Dr J Fuller) two other surgeons and a dispenser were invalided soon after reaching the theatre of war Dr A Farquhar the deputy inspector general then took charge of the mission

*When the mission reached* the Black Sea Omar Pasha had transferred the bulk of his army to the Trebizond district so as to relieve the Russian pressure on Kars The mission therefore moved to the new area: a small detachment was left to organise a field dressing station with the fighting troops while the main body took over the Turkish hospitals at Trebizond and Sinope Conditions in these establishments were chaotic and the records showed a death rate of between 80-90% of admissions The British mission took charge in November 1855 and the following figures cover the seven months they were in control

| *Unit* | *Admitted* | *Died* | *Discharged* | *Remains* |
|---|---|---|---|---|
| Field dressing-station | 111 | 17 | 40* | |
| Trebizond hospitals | [illegible] | [illegible] | [illegible] | 44 |
| Sinope hospitals | 120 | 4 | 116 | |
| Total | [illegible] | 391 | [illegible] | [illegible] |

* Evacuated to hospital

When the mission ended their duties in May 1856 and returned to England the mortality rate had thus fallen from over 80% to under 15% The statistics of this outstanding achievement, which have been taken from Dr Farquhar's official report have never been published but in view of the criticism at that time of the Army Medical Department in particular and of the medical profession in general it would seem only just to place them on record even though they relate to a century ago

### *A Running Commentary by Peripatetic Correspondents*

I'm glad you like the Guidance Clinic,
Sophisticated little cynic,
I'm pleased when you are in a paddy,
It shows you sometimes hate your Daddy
And when you smash up all the lights
It hints at guilty thoughts at nights
You kick my shins and spit at me
Oh *don't* we have a jolly spree ?
But sometimes, sweet delinquent, dear,
You go too far, and then I fear
Your Father figure's gentle smile
Is like that of the crocodile,
Whose overt attitude to fishes
Does not reflect his inner wishes
When cold and tired, with empty belly,
I'd like to beat you, dear, to jelly
*Moral* —Do not put your question to experimental test

* * *

" Many Afghans," a friend from Kabul writes, " are worried, and sometimes caused great pain, by an ailment peculiar to the country, which only their local doctors can diagnose or cure—fallen navel "  If the navel has slipped out of place (that is, is not in correct and equal measurement from the nipples) a specialist is called in to manipulate it back into place  Science and engineering having abolished distance, I feel that cases may, at any moment now, appear in this country  Perhaps we have already overlooked sporadic outbreaks  We should be prepared  I myself am ready with the apt, euphonious, descriptive term " omphalolisthesis "  I am also providing myself with a slightly stretching measuring-tape—made to my own design by Messrs Uppe Bros  Plastic surgery should be on its toes to replace clumsy and painful manipulation by accurate and effective omphalentoporrhaphy or omphalopexy, to be performed under spinal anæsthesia and, of course, in the shade of the indispensible *umbrella penicillinæ*  That 'll show 'em Better fifty years of Europe than a Cycle of Cathay

* * *

The soft airs of the Fortunate Islands are very restful after the rigours of the English winter  From the air the islands spread like mould-eaten bacterial colonies with twisting lagoons, white inlets, and black, ship-tearing rocks

Captain Anson[1] set off from these islands in 1740 with a small fleet of ships only partly crewed with trained seamen  The military complement consisted of five hundred Chelsea pensioners, and two hundred and fifty untrained marines who had not yet been allowed to fire their guns  Less than a tenth of his men survived his trip round the world, and he returned with only one of his fleet of six ships, but with an immense fortune from the treasure ships of Spain  He was full of ideas about the ætiology of the diseases which decimated his crew, particularly the scurvy  Fluxes and tenesmus, he correctly observed, were associated with the filth below decks, and with touching at certain ports  But scurvy was the worst peril, men dying in their tens each day as they rounded Cape Horn and beat their way up to Alexander Selkirk's deserted but beautiful island

The scorbutics bled from their gums and died of obstinate constipation  Their old battle wounds broke down , and in one pensioner a bone healed for fifty years fractured again spontaneously, the callus melting away  The disease carried with it a fatal melancholy—which is not surprising since it was, one feels, more dangerous than shipwreck  Increased danger, or " fatal rumours " caused an increased mortality among the scorbutic  The disease was as severe during the Pacific crossing when fresh fish was eaten daily as it was on the Atlantic voyage on " hard tack "  The patients recovered rapidly after being put ashore, though many died during the transfer from the ships  But patients who had received a boatload of fresh vegetables a week before the weather allowed them to land did not sustain this mortality  This puzzled Anson who was as full of views on scurvy as were [illegible] contemporary literary seafarers  He realised that limes came into it somewhere, but obstinately stuc view that landing on shore was the only true cure he believed, was ill adapted to the foreign element waters, requiring the insensible vapours of terra full health

## O & M

That O & M's home stamping ground
be carefully protected
each Civil Servant's moved around
ere too much is expected.

Yet you and I can't leave our pitch
to follow their example,
so surgeons will be paid per stitch,
physicians priced per sample

New methods will apply, or should,
(Review teams are quite passé)
and endless belts of plain steam pudd,
will oust the marrons glacés

Sweet secretaries were bad for " firms ",
machines, they say, are better,
for pool typists' medical terms
may brighten up the letter

So, fresh the eye and blank the mind !
Let time checks be abundant !
If Deaths and Discharges drop behind,
some staff must be redundant

# Letters to the Editor

## THE MALNOURISHED COMMUNITY

—I write to support Professor Platt s excellent ealistic views (Nov 6) on infant feeding in tech under developed tropical countries

ne rightly says a most important practical approach alnutrition *in this type of community must* be gh the mother and child at the maternity and health centre Unfortunately at present a large rtion of these centres are being rendered valueless lack *of appreciation of the necessity for methods* different from those employed in Europe and North ca To understand this it is necessary to apprec o fact that all pædiatricians and others engaged in ype of work—of whatever nationality—have either trained in the West or have used textbooks written ly on Western style infant feeding When coming ntact with the nutritional problems and feeding ces in the tropics, the pædiatrician with this type of ng is almost always unaware of such aspects of the t as the disadvantages and overwhelming advan of prolonged breast-feeding the scarcity or e (or in some regions the dislike) of animal milk he effect of beneficial and deleterious food pre s Without exception he then passes through a e of bewilderment until he realises that the hed methods learned at medical school are inapplic nder the very different socio-economic and cultural ions found in most of the technically under ped areas of the world Following this two s may be followed—either a cautious attempt to y his teaching in the light of local reality or disas y the adoption of an ivory tower attitude by Western-style instruction on infant feeding nes to be dispensed without either meaning or

correct approach to the teaching of methods of feeding in most under-developed tropical regions at must be remembered, this embraces the majority world's child population) may be envisaged in the ing logical stages

nvestigation of local methods in use in the particular with especial reference to customs, taboos and food ces not only in infant feeding, but also *during* ncy and lactation

*Unprejudiced* analysis of the value or otherwise of methods in their particular cultural and geographical with especial reference to the availability of animal

Teaching of methods of infant feeding based on ole local customs, modified or improved if necessary entific knowledge together with the elimination of il practices. (As an extreme example it may be noted parts of Africa no cattle can be kept at present because tsetse fly In those circumstances where absolutely no milk is available prolonged breast feeding is a bio necessity but can in all probability be improved as he yield is concerned by ensuring that the mother is as d as possible on a diet of locally available foods At me time an undesirable aspect of this practice which be discouraged is the custom of breast feeding an when the mother has become pregnant again )

lly I would like to endorse Professor Platt s tions that the two main initial items in a pro e of infant and maternal care in a malnourished l community are the selection of suitable foods ially vegetable protein foods) for mixed feeding and sign of a diet to enable the mother to lactate ately for two years or even longer These are not ts of interest only to a few anthropologically d pædiatricians but the top problems of infant on in the world today

etta D B JELLIFFE

## MYOCARDIAL TOXOPLASMOSIS

SIR —Dr Paulley and his colleagues reported [1] a series of cases of toxoplasma myocarditis in which the diagnosis was based on serological findings alone In their cases the dye test of Sabin and Feldman and the complement fixation test were both positive both were done as a routine because of the well known non-specificity of the dye test

The interest aroused by this report was shown by the number of sera which were subsequently sent to this laboratory for examination for toxoplasma antibodies from patients with obscure myocarditis In one of these the dye test was positive at 1 32 and the complement fixation test positive at 1 8—findings thought to be diagnostic of toxoplasmosis The patient died a short time later and through the courtesy of Dr Alun Williams I was able to examine a part of the myocardium The well washed and finely ground myocardium was injected intraperitoneally into mice and on the 10th day after primary inoculation abundant toxoplasmas were seen in the mouse peritoneal exudate and passaged from it

This finding emphasises the association between the presence of toxoplasmas in the tissues and of toxoplasma antibodies in the serum and lends weight to the belief based on the serological findings that the cases of myocarditis described by Paulley et al were in fact caused by toxoplasmas

## VENEREOLOGY AND DERMATOLOGY

SIR, When the National Health Service became effective in 1948 venereology was established as an entirely separate and independent specialty a decision which was based upon more than thirty years experience of the venereal diseases scheme and received the approval of almost everyone Since that time there has been a fall in the incidence of first infections with venereal disease an expected development which certainly owes more to peace and full employment and to the efficiency of the service than to new remedies It is clear that some of our administrators are regarding this fall in incidence as an indication that the problem is solved and as an opportunity for saving money Recently a dermatologist was appointed to take over clinics in East Anglia from a venereologist the appointment being advertised under the heading of dermatology although most of the sessions were in venereology

Now comes this advertisement relating to East Kent and Dr Erskine (Jan 8) puts in some special pleading for the suitability of a *combined appointment in thi* area on the rather confusing grounds that (1) there is not enough work to hold the interest of a venereologist in East Kent (2) it is a bad thing to have too much specialisation and (3) a senior registrar in venereology can become competent as a consultant in dermatology by spending part of his time in the dermatological department when working in venereology

Of course it is a good thing for a venereologist to know something about dermatology just as it is a good thing for him to know even more about general medicine cardiology neurology and psychiatry But part time work for three years will not make him an expert in any of these subjects and Dr Erskine s registrar is to be congratulated on his wisdom in not applying for the East Kent appointment

Surely Sir since the principle that the two subjects should be separated has been accepted the appointments in dermatology and venereology in East Kent should be separately advertised and filled by different consultants If as Dr Erskine says there is not enough work for a venereologist in East Kent an area which has large centres of population and important seaports, the explanation may be that clinics are inadequate or badly sited, or that there is not a proper liaison with other departments of the hospitals concerned The late manifestations of venereal disease are commonly to be found among general medical cases and in other special departments If the venereologist has the right degree of interest in his work his colleagues will be anxious to seek his advice and help If, on the other hand, he belongs to some other special subject and has only perfunctory interest in venereology no one will want his advice The result will be a poor standard and a break up of the organisation which has been built up gradually with labour and tears and has produced such excellent results

## FAILURE OF GLYCYRRHETINIC ACID TO CONTROL ADRENAL INSUFFICIENCY

SIR,—Since Molhuysen et al [1] in 1950 first reported the deoxycortone like activity of liquorice extract, a number of papers have appeared describing the effects of liquorice and liquorice extracts in patients with adrenal insufficiency Several authors [2–7] have described patients with Addison's disease who have been maintained satisfactorily on liquorice extract or glycyrrhetinic acid

In a previous communication [4] we described a patient, a woman of 45 with Addison's disease, whose response to the administration of 50 mg of glycyrrhetinic acid four times daily was in some respects similar to her previous response to deoxycortone injections and cortisone by mouth Eight months after implantation of cortone and testosterone pellets, when these were to be exhausted, a course of treatment was begun glycyrrhetinic acid, 250 mg daily It was hoped it would be possible to maintain her satisfac liquorice derivatives alone, and she received no specific treatment for nine months She re apparently well during this time, but was then a to hospital in a severe addisonian crisis We re alarming experience so that the utmost care may b by others using these preparations in the mana of adrenal insufficiency

In July, 1952, this patient had been admitted to and in September, 1952, she was discharged with 300 mg of deoxycortone acetate and 100 mg of testo She remained tolerably well until May, 1953, by wh the pellets were considered to be exhausted. For the she was given capsules of lactose as a control, and for ten days glycyrrhetinic acid (250 mg daily) was sub As further supplies were temporarily not available, p glycyrrhizinate (500 mg daily) was given instead for th ing four weeks, and this in turn was followed by "dummy" capsules Her condition deteriorated two weeks she again began to take glycyrrhetinic mg three times a day She continued with this following five months, when the dose was increased mg daily Two months later she developed a co three days became drowsy and finally comatose, state she was admitted to hospital

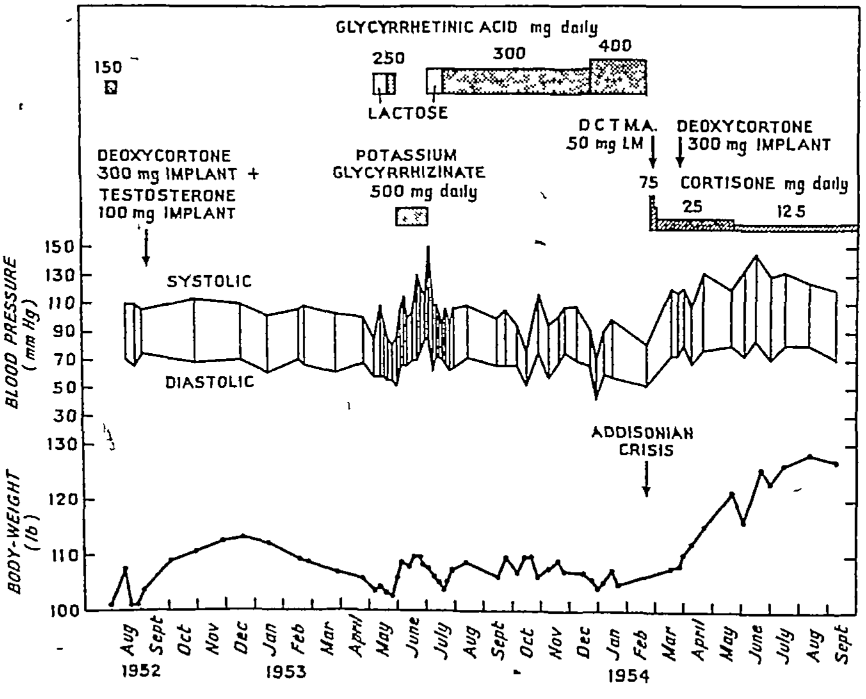
She subsequently claimed that she had taken the of glycyrrhetinic acid up to the day on which she w coma, and her husband confirmed this independently

When admitted to hospital she was deeply cold, cyanosed extremities Axillary temperature was and four hours later 100 3°C Her pulse rate was 110 and blood pressure 90/60 mm Hg Serum sodium centration was 111, serum potassium 3 8, and serum 92 5 m eq per litre, the blood sugar level was 100 ml

She was given intravenous glucose and saline with and intramuscular injections of deoxycortone and acetate Within seven hours her blood pressure had 130/90 mm Hg, she was sufficiently conscious to call use a bedpan, and was complaining of headache. She 1950 ml of urine in the first fifteen hours after admis hospital

Within three days she had recovered and thereafter her gress was most satisfactory has since been maintained implant of three 100 mg p deoxycortone and 6 25 mg isone twice daily by mouth changes in her weight and pressure are shown in the panying figure In her own she "has taken a new lease and has not felt so well for years She is in no doubt general condition on and cortisone is incomparably than while she was taking rhetinic acid, though at the we recorded her statement was "feeling fine

We are satisfied that patient developed acute insufficiency following a time when, as far as ascertained, she was dose of glycyrrhetinic which she had been ma in health for several mon was remarkable that, she had had no diarrhœa apparently vomited only her serum sodium concen had fallen as low as 111 per litre while at the



weight and blood pressure in response to various forms of treatment (D C T M A = microcrystalline suspension of deoxycortone trimethylacetate)

erum potassium concentration was also depressed 3 m eq per litre and later fell as low as 2 4 m eq tre. We attribute the initial low serum potassium ntration in this patient with Addison's disease ie glycyrrhetinic acid, but this deoxycortone like conflicts with its failure to prevent the serum m from falling to the unusually low figure of n eq per litre. A similar paradox was noted by h and Alpert [4] in one patient treated with syrup quorice who showed increased potassium excretion alternate positive and negative sodium balance.

view of the patient's subsequent progress it is that when she was having glycyrrhetinic acid her ition was much less satisfactory than when later vas given deoxycortone and cortisone. It is unwise neralise on experience with one patient but we that glycyrrhetinic acid alone is not a suitable itute for conventional treatment in more severe of Addison's disease. We do not suggest that rrhetinic acid or crude liquorice preparations are pharmacologically active but rather that for some nts they may be inadequate as the sole form of ment, much as deoxycortone alone is inadequate he proper maintenance of patients with adrenal ficiency. Neither deoxycortone nor glycyrrhetinic has any appreciable effect on carbohydrate meta m and cortisone or hydrocortisone is required to ct this deficiency. Molhuysen et al [1] and Borst [2] found that some patients with Addison's disease l to respond to treatment with liquorice derivatives. t is possible that with the development of the disease atient had become unresponsive to the drug.

rst et al [3] have described a synergism between rrhetinic acid and cortisone, though Hart and urd [5] were unable to confirm this. We wonder fore whether those patients with adrenal insufficiency have apparently been satisfactorily maintained for periods on glycyrrhetinic acid may not in fact have secreting small amounts of adrenal cortical hormone without the addition of glycyrrhetinic acid l have been insufficient to prevent symptoms of al insufficiency. There is of course the possibility our patient had neglected to take the drug; or atively that if the dose had been considerably r she might not have developed an addisonian

are grateful to Dr Wm. Mitchell of Messrs. Stafford & Co., Ltd for supplies of the liquorice derivatives used.

## FLUOROACETATE POISONING

t.—As you say in your annotation of Dec 18 on control of rats and mice sodium monofluoroacetate ngerous to mammals. Yet if properly handled by ed personnel it can perform its function and do no to man or domestic animals. This anyhow is the rience of one group of commercial specialists over years, during which there has been no evidence of ity to the operators or to animals other than rats mice.

tterly we have been working on a derivative of sodium acetate fluoroacetamide which tested pharmacologically ts and mice proves to have an L.D$_{50}$ about twice that of m fluoroacetate (about 4 mg per kg for the amide g per kg for the sodium salt) and moreover to produce mild symptoms of toxicity and none of the epileptiform lsions characteristic of sodium fluoroacetate poisoning. his reason fluoroacetamide has now been suggested as a rodenticide in place of sodium fluoroacetate and details hortly be published. Although its toxicity is less than of the sodium salt it is, it appears quite sufficient to it an effective rodenticide.

It is now well established by the work of Sir Rudolph Peters [1] that the toxicity of sodium fluoroacetate is due to formation in vivo of fluorocitric acid and it is our suggestion that fluoroacetamide is only slowly converted into this toxin as compared with sodium fluoroacetate thus giving only small blood-concentrations of fluorocitrate (sufficient to kill rodents but not sufficient to cause violent death) and a larger margin of safety in use. It is of course to be hoped that antidotes to fluoroacetate poisoning will continue to be sought; fluoroacetamide may be more likely to yield to treatment than sodium fluoroacetate in view of the probably lower blood concentrations of fluorocitrate when amide is used.

It is well known that the higher mammals are less susceptible to fluoroacetate poisoning than are rodents. Professor Adrian has taken a dose of sodium fluoroacetate sufficient to produce a urine toxic to guineapigs. For monkeys the L.D$_{50}$ is about 15 mg per kg.

Recently Saunders and Hughes [2] have shown that enzyme degradation of a C–F bond is possible; this, too leads us to a more optimistic view about the possibility of antidotes to fluoroacetamide and fluoroacetate poisoning.

Consulting Chemist

Romford Essex

## HEAT TO THE HEART

SIR,—Some eighteen months ago I discovered that heat applied to the cardiac area very quickly relieved an attack of angina and if applied sufficiently soon it would completely abort it. The means used were either an electric pad (the smaller the better) such as are sold for use in bed or a face cloth or handkerchief wrung out in very hot water. The latter method is quicker but requires frequent renewals and the handkerchief must be 110 F on application to be effective (just a little hotter than can comfortably be tolerated on one's own bare arm—not by a nurse's hand). The handkerchief may be used while the electric pad is heating up. The relief obtained is augmented by sips of hot water or hot tea. The pain is relieved much more quickly though perhaps not more certainly than by glyceryl trinitrate and the method is more reassuring to the patient and may be preferable. In some circumstances it may be the only one available (even if the patient is out in a car a handkerchief can be dipped in the radiator or hot water obtained from a nearby house).

There is also no doubt that cold can precipitate an attack. That there may be a fundamental principle involved is now suggested by the work of Andjus at Belgrade confirmed by Smith et al and quoted in your survey on experimental deep hypothermia.[3] Andjus found that in extreme hypothermia cardiac arrest in animals occurred at 0°C and that by warming the whole body plus artificial respiration the animals could not be revived; and they all died. He then discovered however that if heat were first applied *locally* to the cardiac area (for example by putting a heated metal object on the skin) and if this was combined with artificial respiration the heart began to beat again and the animals recovered. Thus the risk of anoxia of tissues (including the brain) during re warming could be avoided. That is to say keep the general metabolism of the animal (patient) as low as possible supply oxygen and stimulate *only* metabolism of the heart and spontaneous revival becomes possible.

Angina may be regarded as a threatened cardiac arrest and cardiac arrest may be induced by hypothermic and hypotensive drugs. In any of these threatened emergencies it would therefore seem logical to apply heat *locally* to the cardiac area as a first step accompanied by full use of oxygen and perhaps cooling of the head by ice-cold water in order to reduce cerebral metabolism, and so perhaps avoid the cerebral sequelæ that may follow recovery. People are more right than they wot of when they say there was a struggle between his heart and his head. There is always intense competition in the last resort between the two for glucose and oxygen and if the heart is in extremis it is surely desirable to lessen this competition, and give the cardiac muscle a favourable balance for a few minutes.

## MERIT AWARDS

SIR —Dr Fletcher urges that moneys voted by Parliament for the National Health Service should be used to subsidise research other than that covered by the statute of 1946 as amended I am not belittling research when I say that I believe the proper course would be for Parliament to be asked to increase the present grants for research if it be deemed desirable to increase the emoluments of research workers I consider that the diversion of public funds is the issue

I think Dr Fletcher is wrong in supposing that the merit awards were instituted as a compensation for lost private practice

Sheffield 11 ARTHUR JORDAN

## TUBERCULOSIS IN IMMIGRANTS

SIR,—As far as the Island of Lewis is concerned the paper by Dr Hess and Dr Macdonald [1] was an excellent appraisal of the position as it was 100 years ago, and as it could be in a very few years, but not as it has been from the beginning of this century till now My experience confirms their views and that of others that the Celt is no more prone than other races to tuberculosis, but rather the high incidence and mortality spring from social factors almost entirely—at least in Lewis

The Registrar General informs me that mortality figures for Lewis begin in 1871 Comparative rates for that year are Lewis 92, Glasgow 668, Scotland 398, Orkney 150, Zetland 171 By 1914 Lewis was up to 310, and it ran at a higher rate than Glasgow from 1912 till 1936 Housing in Lewis began to improve in 1930 and the rate fell till 1942, when it was down to 50 but it rose yearly to 162 in 1948 It is still higher than Glasgow, the 1953 rates being Lewis 76 and Glasgow 43

My view that the position from 1900 to 1954 is different is based on the following data

(1) In 1942, when I was in charge of the local sanatorium, youths of 17 who volunteered for work of national importance came to me for examination X ray examination showed that more than a third had tuberculosis, which in many cases necessitated sanatorium treatment The youths called to H M Forces did not have an X ray examination Many returned after a few months' service, discharged because of tuberculosis Had they had an X ray examination on call up they would never have been accepted Of 225 deaths since 1940, 64 were in Service personnel

(2) In 1949 a tuberculin sensitivity survey carried out among all school children (4000) and in youth clubs, factories, offices, shops, &c , yielded very high positivity rates 5–6 years, 18% , 5–12, 26% , 15–20 69% , 21–25 81% , 26–30, 91% , 30 +, 96%

(3) In every case of tuberculosis since 1950 in a Lewis person who has left the island, I have a record of a positive reaction before they left home

Thus I believe that the islander develops an already existing focus which breaks down under studies or work, rather than that he contracts the disease for the first time in the cities Contrast the following positivity rates after a re survey of school children in 1954 5–6 years, 2 7% , 5–12, 14% It may be thought, as I myself believed in 1949, that my positive reactor rate was exaggerated, but now I am convinced that the results substantially true because, in the case of school- en, I had several hundreds examined radiologically e regional hospital board and many of the children showing definite evidence of intrathoracic tuber have now reverted to negative reactors Further, i case of those over 15 the tests were all intradermal 10, and 100 T U ) and the vast majority reacted to 1

This is why I say that the situation could, in years, become what it is commonly held to be vaccination, I may add, was offered and given to of any age who was negative to 100 T U foll 1949 survey

Stornoway
Isle of Lewis R STEVENSON D

SIR,—When the B C G schemes are fully devel Ireland the problem of the tuberculin negative emigrant in Britain should be largely solved and anxiety at present felt by chest physicians, b Ireland and Britain, allayed Varying degrees of p have been made up to the present Some co have only just begun B C G vaccination, but in others progress is well advanced In Tipperary (N Riding) priority has from the beginning, 1950, given to testing and vaccinating contacts, adole and young adults Vaccination was offered to all be the ages of 14 and 30 years in 1951–52 School-le have been done each year since that time. 65% of estimated total of adolescents between 15 and 19 then dealt with, but the response from those bet 20 and 30 was poor, the average being not much l than 30% However, with the addition each ye school leavers to the general pool a respectable t being built up for the last two years, 85% of t leavers have been vaccinated

It is yet too early, of course, to report results, b figures of new cases of pulmonary tuberculosis occ 1954 are beginning to show a very favourable pictur I believe is due to the vaccination The proportion cases in people between 14 and 29 years, which was 1951, and in the two following years 51% and 4 dropped this year to 38% At the other end, the pro of new cases in those over 40 has risen from 27% to 4 1950 8 new patients were returned from England, e treatment or convalescence In the following ye numbers have fallen to 5, 5, 3, and only 1 in 1954. statistics show some improvement at least in the which obtained four years ago, and I believe that next two or three years there will be greater improve

There are at present two unknown factors which my optimism One is that the youngest age for em from this country is from 17 to 19 years of age vaccination done at 13 in a rural district protect un age when the occurrence of a natural infection in the vening years is not likely? Secondly, we are at using in this country two prevaccinal tests, with 1 in 5 1 in 100 old tuberculin An unknown number of reacting to the 1 in 100 dilution are still susceptible to t losis Already in this county, with our small num cases of primary pleurisy with effusion and a primary c have occurred in young persons who have been rec being positive to 1 in 100 There is no doubt but that future, the strength of the last prevaccinal test will ha cut down

The figure of 14 5% positive at the age of 18, r Flynn and Joyce,[1] should not be taken as general Ireland The figures for Tipperary (N R ) are 10% (2145) , 15, 44% (600) , 18, 55% (400) , 22, 63 25, 70% (227)

From the age of 15 to 24 years the propo females was, on average, 5% less than that for Over that age the figures were nearly equal though the size of the average Irish country t only between 1000 and 6000, there is a striking di between the infectivity-rate in the urban an rural portions of the country In the rural po this county, 41% between 15 and 19, and 53% b 20 and 24, are tuberculin-positive In the to corresponding figures are 72% and 82%

## BED WEIGHING MACHINE

—Dr Flear (Jan 8) and Dr Darmady[1] have not oned the possibility of error in estimating the varia in weight of a patient due to alteration in the ure content of the bed clothes An error due to this be significant Through the courtesy of the burns at the Birmingham Accident Hospital I was able e the Avery weighing machine for the following lment

nattress with bed-clothes and linen were exposed to the d November atmosphere in an unheated part of the al A bed was then made up and heated by an artificial (a steel cylinder of approximately the same surface s the body) and heated by two light bulbs to a tempera f about 100 F between the cylinder and the mattress ed was kept in a room at a temperature of 78 F for eight hours. The mattress alone lost $15^1/_4$ oz the ess and bed-clothes together lost 31 oz.

ese conditions are of course entirely artificial the opposite is more likely to occur in practice resses and bed linen are put into use after being ughly aired and they may fairly quickly pick up ure from the atmosphere or from the patient practical way to overcome this difficulty is to use a ress such as a Dunlopillo, which did not alter eight in a similar experiment, and to remove as n as possible in the way of blankets and linen from ed each time the patient is weighed

## HEARING TESTS

—While agreeing with most of Professor Ewing's rks in his statement published in your issue of 1 on sweep frequency screening tests of hearing ms desirable to point out that partial deafness of everity necessitating special educational treatment d be detected before the age of five years if it is of nital origin Such deafness should be detected ably before the age of one to two years so that the may receive auditory training during the period of al physiological speech development If acquired ess should occur rehabilitation should start straight as soon as the child is well enough.

vould be unfortunate if the impression were given t is satisfactory to defer tests of hearing until the o group tests are done at the age of five The for deafness at an earlier age is long overdue postnatal clinic would seem an ideal place for sing the mother's awareness of the possibility nplications of partial deafness

on, W 1

EDITH WHETNALL.

## REPAIR OF FEMORAL HERNIA

—May I add my testimony to that of Mr Pearce 3)[1] For some years I have also used the supra extraperitoneal approach for femoral hernia[2] o[3] having cited this and seven other perabdominal ls, dismisses them as ' not in general use nd it rapid easy and satisfactory

method is similar to that described by Mr Pearce that it is preferred to reveal the extraperitoneal by divaricating the recti and pyramidales through a ddline incision slightly overlapping the pubis. It is ant to avoid the branches of the epigastric and obtura ble by mobilising the sac posteriorly then laterally and anteriorly It is usually delivered from the canal e and may be ligated and dislocated so as to present peritoneum at the femoral ring Like Mr Pearce I nd repair unnecessary and I hope to produce statis lence for this shortly On one occasion it was necessary into a hæmatoma in the infra inguinal fold, and I opportunity to inspect the ring which had closed ously in a few days.

If the hernia is strangulated the neck of the sac must be controlled with clamp or finger to prevent the sanguineous exudate from entering the general peritoneum. If gut resection is necessary (and that is rare) it may be done with ease without extra incision

Ill effects are rare I have had one hæmatoma and one midline hernia, which was in a very old man I have seen a patient with a good result two years after a septic dehiscence of the wound The operation needs a relaxing anæsthetic and is not very suitable for local infiltration. It is better avoided if one is not sure whether the lump may be an inflamed gland It is rather messy in fat patients with old and adherent hernias, but so are most methods.

The main advantages are the ease with which the sac can be excised and high ligated and the stump dislocated and the opportunity clearly to inspect the femoral ring bladder great vessels and if necessary peritoneal contents The approach gives access to all inguinal femoral and obturator orifices I use it for closing the ring of sacular direct inguinal hernias with a nylon gauze prosthesis. It is however hardly worth doing for oblique inguinal hernias unless at the same time as other retropubic operations

## OPERATIONS ON THE HEART

SIR —I must take serious issue with you over your leader of Dec 25 You state that Wilson et al have identified two fundamental types of electrolyte pattern in the cardiac patient the reference being to a paper published in 1954 The existence of hyponatræmic states in patients with cardiac disease has been known for at least six years and a great deal of work has gone into explaining the mechanism of this development most of which bears little relationship to your subsequent discussion

You begin by stating arguments that hyponatræmia represents sodium depletion brought about by a salt restricted diet and on this basis advocate intravenous hypertonic saline But further on we are told that commonly the total exchangeable sodium value is high The question of sodium depletion in these patients cannot be settled by the value of serum sodium alone but must be determined by balance studies and/or muscle biopsy analysis. Depending on how great the hyponatræmia is how much œdema (or extracellular sodium) the patient has and how much sodium has been transferred into cells these patients may be either sodium depleted or have a total excess of sodium in their body fluids as a whole

This is however only a side issue in the electrolyte physiology of hyponatræmia for the studies of Squires et al[1] and Cort and Matthews[2] have shown that such patients have an intracellular potassium deficiency which is partly replaced by an increase in intracellular sodium and water The serum sodium level represents not the state of body sodium stores but the state of extracellular osmotic pressure, which in turn reflects changes in intracellular osmotic pressure If serum sodium concentration is low it reflects a lowering of intracellular osmotic pressure or a disturbance of forces within the cell maintaining extracellular osmotic pressure These patients are indeed ill but it is changes in intra cellular osmotic pressure sodium content and pH that threaten them not the state of body sodium stores The administration of hypertonic saline to patients who have hyponatræmia with potassium deficiency may raise serum-sodium levels for a short time but will soon lead to little more than a further increase in œdema fluid If such patients respond to anything clinically or biochemically it is to prolonged administration of both potassium and protein since both are needed to replace depleted states of the intracellular fluid My own experience now includes the successful treatment of 25 hyponatræmic cardiac patients with extracellular hyponatræmia, hypochloræmia, and alkalosis by this therapy, while the administration of hypertonic saline has led to everything from pulmonary œdema to a tremendous thirst (with water by mouth these patients immediately dilute themselves back to their initial low serum sodium level) Hypertonic saline has led to everything, that is, except a lasting improvement in the patient's bio chemistry The recent demonstration of the relationship of potassium metabolism to the therapeutic action of digitalis only further underlines the importance of metabolic preparation of patients for cardiac surgery, but it must be a detailed and careful analysis

## A BLOOD-TRANSFUSION PUMP

SIR,—I was interested to read in your issue of Nov 13 a description of a transfusion pump by Mr Martin I can confirm his remarks regarding the value of rapid intravenous transfusion, which appears to be as efficacious as the inter-arterial route [1]

I have been using a transfusion pump with the same features as that devised by Mr Martin for the last five years It was described in the *British Medical Journal* in 1953,[2] and has been manufactured for the last two years by the Bax Engineering Co, Wheatley, Oxfordshire I may add that the principle of the flexible tube compression pump has been known for over fifty years, the main difference between the older models and those described by Mr Martin and myself being the inclusion of a method of adjustment of the pump for different tube diameters This improvement avoids the necessity of using special tubing and opening of a transfusion line

## DISTRIBUTION OF CHRISTMAS GIFTS

SIR,—I am sure that your readers will be pleased to learn that the contributions to provide Christmas gifts for the beneficiaries of the Royal Medical Benevolent Fund amounted to £2775 We were able to distribute £8 to each of them

The warmth of gratitude expressed in letters of thanks would have gladdened the hearts of the contributors

WEBB JOHNSON
President
London, S W 15
Royal Medical Benevolent Fund

## THE LABORATORY TECHNOLOGIST

SIR,—As medical laboratory technologists we feel that Dr Davey's article of Dec 11 cannot be allowed to go unchallenged

We feel that the present-day technologist has sufficient understanding of the techniques available to him to make an intelligent appraisal of them and that he therefore will not take the short cuts Dr Davey mentions It is only in those laboratories in which a thorough training (theory as well as practice) is not provided that the situation he describes can arise Furthermore, technologists are not in the habit of taking unfair advantages of their medical associates We are not such a Machiavellian band

The present-day entrant to medical laboratory technology is, and should be, an intelligent person, and he is as capable of reliable and honest work as a medically qualified person If this were more generally understood and accepted, relations between the clinical pathologist and technologist would be easier It is the seeming lack of mutual trust that is driving away the more suitable entrants into other fields

Professor Bedson, in an address to the London branch of the Institute of Medical Laboratory Technology, spoke of the increasing difficulty in finding suitable male entrants He suggested that an increase in salaries would overcome this problem Such an increase would certainly be appreciated, but there are those who fe improvement in status would be of greater val

Dr Davey's article certainly does not help to the problem of recruitment

## THROMBOPHLEBITIS FOLLOWING INTRAVENOUS INFUSIONS

SIR,—Mr Jones's experience (Nov 6) must b shared by most of us in greater or lesser degree time to time attempts are made to incriminate factor, and the current favourite appears to b phurous compound in the red rubber of the giving set There are so many variables in this f only by pooling knowledge can definite concl reached My object in reporting my own (ad incomplete) investigations is to stimulate spread inquiry

The general aim should be to eliminate ea factor in turn by studying large numbers of co infusions The factor investigated in my own was red rubber I first studied 79 infusions in 46 p using the standard Regional Blood Transfusion drip sets, a similar study was then made of inf which plastic tubing had been substituted for r

A robust dripper was made by Mr Watts, of Ham Hospital technical staff, who modified a 'Plim that the sizes of 'Polythene' tubing then availab would fit the lower end Mr Watts also made metal adaptors to connect the polythene tube to needles The apparatus was unpopular in the theatr the anæsthetist was unable to use it for intravenous so a two way tap was added to the needle in the t removed before returning the patient to the war

Cold polythene does not compress easily, so th was controlled by altering the height of the bott infusion is not possible with the smaller sizes of p but I understand that larger sizes are now availab

Only 10 infusions were given with polythe but the fact that such drips were not entirely fre suggests that something other than rubber is the ca problem On the other hand, in 5 of the 10, there reactions, in 5 there was only simple thrombo reaction), and in none was there any pain, re tenderness (moderate and severe reactions) The f the rubber series were 15 (19%) with no reaction l with mild reactions, and 47 (60%) with moderate reactions

The results once again emphasise that infusion eight hours' duration are the ones likely to give

Of the 15 rubber tubing infusions without reactio lasted more than eight hours, and of the 5 plastic infusions without reactions 3 lasted less than eight lasted nine hours, and 1 lasted twenty four hours T is not the complete answer is shown by the 14 ca reactions after infusions lasting eight hours or les case the reaction was severe Of the 17 cases w reactions after rubber tubing infusions, 13 had had of ten hours or less, whereas in none of the 5 cases w reactions after plastic tubing infusions had the infus less than ten hours These results show that infusions through rubber tubing are more danger prolonged transfusions through plastic tubing

It was impossible to say whether the type of flu influenced the incidence of thrombosis, since the transfusions were usually of short duration w dextrose or saline infusions were more prolonged was no apparent association between the type o or length of operation and drip thrombosis. Mo half the patients were between the ages of fi eighty there was no obvious connection severity of reaction and age In 12 cases it is that a mask was worn while setting up the drip of these had no reaction 11 transfusions were in the theatre and only 1 of these (a two hour was trouble free Records of dressings applied re site are incomplete but it is certain that some with no dressing had no reaction and some with ito sterilisation had severe reactions There seems loubt that the reaction is not an infective process. 3 cases cannulæ were used on forearms, and 3 ped severe reactions In 4 cases cannulæ were used les, and in all severe reactions developed support ie common belief that reactions in the leg are oner and more severe than those in the arm of the leg infusions lasted less than twenty hours imber of severe reactions with cut-down trans s was much higher than with simple needling and innot be explained satisfactorily by the time factor ie the number of needle drips running for twenty or more without more than a moderate reaction most a third of the total

## SANATORIA

—In tuberculosis as in all diseases, we have to pecific as well as constitutional methods of treat —the first indicated by the disease the latter ed to the psychophysical personality of the patient the object of raising his resistance The specific ds of treatment (antibiotics, chemotherapy and y) are the greatest help but they cannot alone ce a complete cure and constitutional methods always be the centre of our endeavours.

stitutional methods cannot however be vaguely sed as mental rest pure air adequate nutrition. t work on metabolism endocrinology neuro ative physiology and medical psychology allows more precise knowledge of the human constitution ius for a more accurate picture of the constitutional s of each particular patient This makes for a more al application of dietotherapy climatotherapy otherapy and of certain constitutional pharma al agents The sanatoria are institutions where onstitutional procedures are applied and they have ihtedly rendered great service

s fact that sanatorium treatment has often been d on wrong psychological lines—as that novelist dius Thomas Mann showed in his *Magic Mountain* s not mean that such treatment should be aban Sanatoria will always be useful but their methods to be modified because whereas even a few years inatorium treatment was everything in tuber s treatment today it is only one factor in a complete therapeutic constellation and in sanatorium treatment the new knowledge of constitution should be taken into consideration.

## CANCER OF THE LUNG

Sir,—The absence of any mention of a relationship between cigarette smoking and lung cancer by the chief medical officer of the Ministry of Health in his annual report is certainly difficult to understand Although most members of the public have now heard of this connection it is surely time that more authoritative advice was given to them and the same kind of effort and initiative which was put into the successful campaign against diphtheria should now be directed against lung cancer Although other factors may be important few can seriously doubt that cigarette smoking is the most important

Apart from the work of Bradford Hill and Doll Hammond and Horn[1] have produced convincing evidence from the United States In a study of 187 766 white males between the ages of 50 and 69 they found that the death rate in all smokers was 52% higher and amongst heavy smokers 75% higher than in those who had never smoked The higher death rate in the smokers was largely due to cancer of the lung and coronary disease Such evidence emphasises the need for the widest education of the public on this subject

London W 5

Keith Ball

## ENDOCARDIAL FIBROSIS

Sir,—I was interested to read Dr Still s article of Dec 18 I suggest that this condition should have been called endocardial fibro elastosis a the prominent feature is the presence of generalised endocardial thickening with proliferation of both collagenous and elastic tissues In adults mural thrombi with resultant emboli can occur The myocardium is usually normal though patchy myocardial fibrosis is sometimes also present

This condition should not be confused with endomyocardial fibrosis found in East and West Africans Endocardial fibro-elastosis in infancy is associated with other congenital anomalies—i e., hypoplasia of the aorta bicuspid aortic valves coarctation, patent ductus and aortic and mitral stenosis due to involvement of the endocardium of the valves by the same process. Some of these were also present in Dr Still s cases. *There is a family history of congenital heart-disease in* 20% of those cases[2]

Gowing[3] mentions that most affected children died in the first year of life though Dr Still says that sudden death due to this cause in infancy is not widely recognised in this country I should like to point out that this condition can also occur in other age groups. White and Fennell[4] described two cases in men aged 71 and 50 both of whom suffered from angina pectoris and eventually died of congestive heart failure Thomas et al[5] have described 20 cases with necropsy reports and have arbitrarily divided endocardial fibro-elastosis into three groups—infantile (under 2 years) childhood (between 2 and 16) and adult (over 16) The hearts in all of the cases in this condition are usually enlarged and the electrocardiograms show various arrhythmias heart blocks and ST changes The clinical picture may also vary in different cases

Although as Dr Still points out the ætiology is unknown Johnson[2] has put forward an interesting suggestion that endocardial fibro-elastosis results from anoxia of the endocardium due to premature closure of the foramen primum or foramen ovale at an important stage of intra uterine life This condition has also been discovered in stillborn infants

## LYMPHŒDEMA PRÆCOX

SIR,—Having read your annotation of Jan 1, we would like to draw attention to a recent publication[1] by ourselves on the treatment of this condition Although the decision to operate must remain an individual one, it should no longer be necessary to reserve radical excision for the huge leg Size alone is an inadequate criterion of operability, and other factors, particularly the recurrence of acute erysipeloid attacks, are of equal importance

The technique which we have described allows the whole of the subcutaneous tissues of the lower leg and the dorsum of the foot to be excised and grafted at one operation lasting just over one hour During the excision, bleeding is prevented by using a pneumatic cuff tourniquet and neither hæmorrhage nor shock has been a feature It is therefore justifiable to offer operation to patients with relatively mild degrees of lymphœdema

J SCOTT TOUGH

## ARTIFICIAL HIBERNATION IN POLIOMYELITIS

SIR,—In the Brunswick epidemic of poliomyelitis in 1952 62 early cases were treated with continuous sedation, using the barbiturate 'Somnifaine'[2] Paralysis developed less frequently, and was less extensive, than in a control group of patients who did not receive the drug

In view of this I suggest that it would be worth while investigating the effect on poliomyelitis of artificial hibernation, since each constituent of the "lytic cocktail" has a relevant pharmacological action During the phase of "minor illness," and in the preparalytic stage, chlorpromazine and promethazine would sedate the patient and rest the motor neurones, without endangering the brain-stem centres Chlorpromazine relieves pain and induces a feeling of euphoria—both beneficial effects in the paralytic stage of the disease, especially when the patient has to have artificial respiration In bulbar respiratory paralysis chlorpromazine would, by lowering the basal metabolic rate, decrease oxygen consumption and so lessen the risk of anoxæmia The analgesic effect of both chlorpromazine and diethazine would reduce respiratory pain and allow deeper and more regular respiration, and by their atropine like action chlorpromazine and thiazinamium ('Multergan') would diminish the mucous secretions in the respiratory tract

Brunswick Germany

TH BREHME

## "TAKE A COUPLE OF FAT VIPERS"

SIR,—With reference to Francis Steer's observations on viper wine, the therapeutic administration of the viper dates from antiquity, it was used by the Emperor Nero's physician and its virtues were extolled by Galen

Dr Lyonnet[3] tells of a letter written in 1675 by a French noblewoman which included a recipe for the preparation of a soup made from vipers Fat of the viper was claimed to have aphrodisiac properties, and its dried liver was said to stimulate contractions of the uterus Preparations including the viper as a constituent were still contained in the French Codex of 1908 The medicinal value of the viper has not as yet been substantiated, but it seems unlikely that any modern physician would deem it necessary to undertake a therapeutic trial

The Royal Free Hospital
North Western Branch
Hampstead London N W 3

F CLIFFORD ROSE

SIR—Those who are attracted by Mr Steer's suggestion to "take a couple of fat vipers" may be interested in the following recipes taken from *The Dispensatory of the Royal College of Physicians, London* (1746)

JUS VIPERINUM

Take a viper of a middle size without the skin, head or ntrails of water a quart Boil to about a pint and a half, remove all from the fire, and when the water is col viper be not a dried one, take away the congealed fa take a chicken of a middle size drawn and the skin wit fat taken off, and put it whole into this decoction wh set it upon the fire till it boils, then remove it from take out the chicken, cut the flesh of it into small piec put again into the water and set it over the fire but as it begins to boil up pour it off, first having tak whatever scum may have risen

VINUM VIPERINUM

Take of dried vipers two ounces, of white wine thr Infuse with a gentle heat for a week, and then wine off

Surbiton, Surrey

## APICAL LOCALISATION OF PULMON TUBERCULOSIS

SIR,—I cannot agree with Dr Cudkowicz's tion (Dec 25) of this phenomenon, with regard has been called "post primary" tuberculosis.

The apical pleural bronchial artery may have a course, but the primary pulmonary tuber does not have a constant position, and may b in any part of the lung Thus there is no the lymph node component of the primary (unless extremely extensive) will be in constant to any small hilar vessel The enlargement and of the bronchial arteries come afterwards, when lesion is of some standing, but are in no way tuberculosis They may occur in any chron disease accompanied by the formation of new tissue—e g, bronchiectasis and pneumoconios

When we come to consider apical "adult tuberculosis generally, we find that doubt h thrown on the view that such a lesion is nec preceded by a childhood infection[1] There is that tissue maturation alone may dictate adult-type apical infection Dr Cudkowicz's will not account for such a case

I feel that the weight of the present evidence the opinion that oxygen lack is the most imp factor

Department of Pathology
Llanelly Hospital

## ARTHUR KEITH

Kt M D Aberd D.Sc LL.D., F R C.S F R.S

IEN Arthur Keith was appointed conservator of the erian museum of the Royal College of Surgeons of nd he was already known to his own profession outstanding anatomist and embryologist. At the ge he won general recognition as an anthropologist Darwinian evolutionist.

was born in 1866 on a small Aberdeenshire farm of the ten children of John Keith 'At the country ols where he began his education he made an pressive showing He was only too willing to upt his lessons to help his father with the harvest when he was 16 he left school to learn to be a farmer the tales of a student who lodged with the Keith y led him to think there might be something in an mic life after all His Latin and the family held, were so poor he could never hope to enter the aculty, but with two years hard he might manage to enter as a nt of medicine His father d him a 'wraith' (term) in leen at Gordon's College to see he could make of it.

1884 after this hesitant start, tered Marischal College where e later wrote John Struthers ned the Darwinian gates for Keith carried off the anatomy prize—the sixth edition of the *of Species*—but he was not one truthers's favourite students ps because he frankly admitted he learned more in the dissecting than in the lecture-room His died at the beginning of his al studies and the major bur hat he won when he topped the rship list eased the family es. In 1888 he took his M.B the highest honours and was led the John Murray medal as ost distinguished graduate of ear

1889 after a few months in general practice he ffered on the recommendation of his professor of y an appointment as medical officer to a mining ny in Siam The flora of the region was imper known and it was essential that the candidate from his medical duties should collect botanical mens for Kew Gardens. At his post at Paron Keith that 80% of the villagers suffered from malaria ransmission by mosquitoes was still unknown o began to dissect monkeys to discover whether were infected His old love of anatomy reasserted and he became a subscriber to the *Journal of my* which he was later to edit He sent some ens to Kew but his real goal was now anatomy e returned to England in 1892 with £150 of savings tinue his studies in the London medical schools.

ides his formal studies at University College in ation for the F.R.C.S he began to read the literature ape world of which his dissections in Siam had him first hand experience Professor Thane gave small room at University College and he obtained es of the primates from the Zoological Gardens to h his data from Siam As an early result of these s he was awarded in 1893 the Struthers medal ze of the University of Aberdeen for his paper ring the ligaments of man and ape The following obtained the F.R.C.S and his M.D degree for his on muscles In 1895 he read Eugene Dubois announcing the discovery in Batavia of a missing Keith came to the conclusion that the fossil skull ntirely human and represented an early stage in evolution From this began his study of the ls of man and his first paper on *Pithecanthropus* was published in *Science Progress* in 1895

The same year the senior demonstratorship in anatomy at the London Hospital Medical College fell vacant and Keith obtained the post. His money was finished and he was desperate to get the job: the entry in his diary ran Got it—thank God; a beginning" Teaching he later confessed did not come easily to him at first but even in those early days he inspired in many of his students, including Frederick Wood Jones, a love of anatomy and research. The following year he was also appointed curator of the college museum and in due course he became joint lecturer and finally head of his department. As a teacher he was anxious to equip his students for clinical practice— I wanted the old practical utility anatomy reintroduced and taught again —and he diverted his research from the evolutionary history of the structures of the human body to their rôle in the living organism In 1901 he undertook a series of X ray investigations to show that the entire diaphragm and not only the right and left domes moved downwards when a breath was taken On this study was based his Hunterian lectures on Glenard's disease (1903) His interest in visceroptosis continued as is shown by the last letter from him which we published (*Lancet* 1953 ii 450). His other work as a practical anatomist included his researches into the mechanism of respiration and into the muscular structure of the heart.

In 1908 Keith left the London Hospital to become conservator of the Hunterian Museum of the Royal College of Surgeons The years at the London had been he held the most critical and profitable of his life but at the College of Surgeons he hoped to be able to turn again to the evolutionary and anthropological problems where his real interests lay He began at once to collect material for an anthropological history and in 1911 he chose as the subject of his Hunterian lectures the Remains of Fossil Man His work at and for the college soon won extramural recognition In 1911 the first and most prized of his six honorary degrees was conferred on him by Aberdeen University, and in 1913 he was elected F.R.S His book on the *Antiquity of Man* was written at this time though it was not published till 1915

The 1914–18 war again shifted the emphasis of his work to practical anatomy War wounds and bone-grafting gave rise to old and unanswered questions and Keith's lectures for these years were published in 1919 with the title of *Menders of the Maimed* In the same years he also published *Engines of the Human Body* But throughout the war Keith continued his anthropological work and as president of the Anthropological Institute (1911–17) he gave four important addresses in which he set out his evolutionary doctrine In 1917 he was appointed to the Fullerian chair of physiology of the Royal Institution which gave him a further opportunity to expound his views. In 1927 as president of the British Association, he reviewed the confirmation offered to Darwin's theories by modern science His growing reputation was shown by the knighthood conferred on him in 1921 The busy round of research writing and lecturing continued till in 1933 owing to ill health he retired from his post at Lincoln's Inn Fields to become master of the Buckston Browne research farm at Downe Here he happily combined work in the study with work in the fields His *New Theory of Evolution* appeared in 1918 and his *Autobiography* in 1950 After the death of his wife in 1931 the interests of the farm furnished him (as he put it) with companionship as well as recreation and the day before he died on Jan 7 he was busy with his pruning hook among the fruit trees

### TRIBUTES

J K writes The value of Sir Arthur Keith's record in the fields of anatomy and anthropology is known throughout the world and wherever the true worth of these sciences is appreciated men honoured and respected him During his long life, packed with such untiring industry and so much rich experience, his contributions inevitably brought him recognition as a worthy successor of Hunter, Darwin, and Huxley, giants of past days, but none of these things could account for that real affection which all who knew him intimately soon discovered they possessed for the man himself

" Like others truly great, neither honours nor achievement changed him. His voice was gentle and soft-spoken, and his transparent humility encouraged those of us who knew so much less than he did to come and slake our thirst for knowledge at the fountain head His lectures in his early days at the Royal College of Surgeons some of us will never forget, and it is their atmosphere, more perhaps than their content, which lingers with us still

" In the old tier-seated theatre, he, if anyone ever did, could make the dry bones live, how he treasured those priceless specimens which he had selected for us with such insight from the museum of which he was the Conservator, and how obviously he enjoyed every moment of the lecture as much as we did! I think ' revelled in ' would be the more apt word to describe the way he spent the all-too-short hour devoted to describing, explaining, and applying the facts of structure and function revealed by each object with its own particular story to illumine a present-day point of clinical application

" Like all good teachers his delivery was natural and completely devoid of tension It gave us the impression of effortlessness No notes were needed, for his princely memory recalled at each succeeding moment what he had already prepared just for that moment as a link in the chain of his exposition or argument, and the impression at the end was that he and we had arrived where we had been told we were going, but that there was still a great deal more our guide could have shown us had time sufficed

" Sir Arthur had that rare gift of being able to make a difficult and complicated subject not only comprehensible but interesting to the uninitiated Those of us who heard his popular lecture at the annual meeting of the British Medical Association in Newcastle in 1921 on the Healing of Prenatal Wounds have never forgotten how with appropriate lantern-slides he made extracts from the story of human embryology not only intelligible but fascinating to the lay members of a very large mixed audience Whether addressing the crowded theatre or in quiet conversation, this great gentleman was always the same happy warrior, characteristically at ease talking about the pursuits he loved and to which he had devoted his life.

" His eyes could on occasion flash fire, for in his contentions for truth his soft-spoken voice could become firm as the grey granite of his native city How firm and yet how kind For this, too, some of us will always gratefully remember him "

R J L writes " During his 25 years as curator of the Hunterian museum, Keith became well known far outside the circle of his scientific contemporaries. His opinions on evolution, and on the nature of man and his place in the cosmos came to be discussed and quoted by many a non-scientific writer He was a staunch Darwinian and an ardent naturalist His reputation spread far and wide, and thousands of pilgrims visited the Museum where he presided like a high priest in his temple He was an accepted authority on human anatomy, but it was as anthropologist and Darwinian evolutionist that he grew to such stature during those years Anthropology and the processes of evolution remained his principal interest until the end of his life

" To visit him in his retirement at the research farm was to find him wearing a battered felt hat, a bird's feather stuck in the hatband, dressed in execrable old clothes, and carrying his four-score years very lightly He was usually engaged in some manual labour about the farm He took a keen interest in the common domestic animals there, having a name for each and studying its character very intently Like most great men he was sympathetic in his understanding and put the most self-conscious person at ease by his natural and ier He was a very kindly man His brain until the end of his life His clean-cut features g gaze marked the incisive brilliance of his o simple commonplace things, and his con- sparkled whether the was highly scientific or concerned the homely things of everyday life general knowledge was profound and his memory pædic His life was active and full until the end remained a trustee of the Hunterian collection continued to write, his last book is now in the

" Few of his contemporaries survive, but a wide of a younger generation, influenced by his charmed by his great personality, will deeply passing "

## CHARLOTTE RHODA BROWN

M D Brux, L R C P E

Dr Charlotte Brown, who died in hospital at on Jan 1 at the age of 86, was one of the early women who qualified in medicine under difficulties despite some opposition

She was a daughter of William Hodgins, of jordan House, co Tipperary, and she never interest in natural history which was bred in her in rural Ireland, in a house with a large garden qualified from the London School of Medicine taking her Brussels doctorate the following year holding several appointments she settled in practice in Bradford, where she was the only doctor, until her marriage in 1901 to the Rev Brown Before the 1914–18 war she did much woman's suffrage movement, and all her life eager to share in any public work in which wome a part

In 1916, she joined the staff of the East Anglian torium at Nayland, and specialised in tuberculosis following year she was appointed tuberculosis officer to the Essex County Council Later she medical superintendent of the children's hosp surgical tuberculosis at High Beech in Epping She remained at High Beech, combining the po a child-welfare appointment, until her retirement practice in 1932 She and her husband then went in Welwyn Garden City, where they took a ver though not a vocal, interest in the activities of neighbourhood

A colleague writes " Dr Brown was a lovable with a large circle of friends in Welwyn. She had a sense of humour, and would tell many stories herself She was excellent company, and her background—the background of the Somerville Ross *Irish R M* stories—gave her an endless anecdote and reminiscence, always very much point, well polished with Irish wit and charm, and kindly and tactful "

# Notes and News

## LASSIFICATION OF PROPRIETARY MEDICINES

HE classification of proprietary preparations which has n undertaken by the Joint Committee on Prescribing is to continued by a standing joint committee of the Health vices Councils. A revised edition of the booklet giving lists reparations classified in categories 1 5 and 6 has been ted and is being distributed to doctors and chemists as uide to prescription under the National Health Service eplaces the lists issued in July 1953 and in January 1954

## REMUNERATION OF HOUSE-OFFICERS

HE Medical Whitley Council (Committee B) have agreed all fully registered house-officers shall be paid at what at present the rate for the third house post—namely 5 per annum They have also agreed that provisionally istered house-officers shall be paid at the rate for the second se post (£475) instead of that for the first house post 5) if they have had suitable experience outside the ional Health Service equivalent to a first house post in service

## FOOT FAULTS

N Dec. 20 Mr W Sayle Creer showed to the general ctice section of Manchester Medical Society a film on *Faults Related to Form and Function* This, he said t with aching and tiredness associated with muscle gue due to over use The film included evidence supporting view that the ligaments of the foot were of paramount ortance the muscles having a subordinate rôle This was traditional English view which went out of fashion when rington showed the importance of reflex muscle action. sed to be said that ballet dancers feet went flat when stood in the relaxed position and their muscles were red Two ballet dancers were shown and it was evident their feet never went flat but merely looked flat owing he ballet shoes The feet of six babies varying in age from lays down to 12 hours showed well formed arches in radistinction to the previously held opinion that at birth es had flat feet, the arch coming into being only by the n of the muscles in the early stages of walking

he lateral stability of the foot depended on the width and rity of the forefoot and it was impaired by narrowness e foot or incompetence of the first metatarsal segment trong foot could be likened to a pair of roller-skates, ng for minimal muscular control a defective foot mbled an ice-skate requiring maximal muscular control op inversion or eversion It was thus overwork and early ue of the muscles that accounted for the symptoms en eye and a critical mind was required in order to assess foot; the standard of normality must be exacting for s *the minor deviations from the normal that had caused* ason When the minor degrees were recognised the cause e symptoms was obvious. Mr Sayle Creer ended with a for greater care of the feet of children because most e were born with healthy feet

## ARTIFICIAL PHOTOSYNTHESIS

Daniel J Arnon professor of plant physiology in University of California announced on Dec 29 at the al meeting of the American Association for the Advance of Science that the process of photosynthesis had been ssfully *duplicated outside* the living plant.[1] He and his iates, after six years research had shown that the ent-containing chloroplasts of green plants could convert on dioxide into sugar even when they were removed the plants cells. Radioactive substances were employed termine the intermediate stages of this process. A new tion— photosynthetic phosphorylation —had been dis red and three catalysts of the reaction had been ified as riboflavine ascorbic acid and vitamin K

## NUFFIELD ORTHOPÆDIC CENTRE

Jan 4 portraits were unveiled of the two men who borated to found the centre Mr A H Smith the chancellor of Oxford University unveiled a portrait of ate G R Girdlestone Sir Robert McCarrison chairman e university s medical postgraduate committee described Girdlestone s orthopædic work was carried out in huts ord Nuffield provided money to rebuild the hospital and s reopened in 1933 as the Wingfield Morris Orthopædic Hospital Prof. J Trueta in unveiling a portrait of Lord Nuffield said that the two men were different in temperament and ideals but between them they had made the hospital what it was today

The portrait of Lord Nuffield by John Whalley has been presented by Lady Nuffield Mr Girdlestone's portrait painted (from a photograph) by Frank Eastman, has been given by old patients and friends

## *CIVILIAN CASUALTIES IN WAR*

THE North West Metropolitan Regional Hospital Board and the Middlesex County Council have lately made a joint study of problems concerning civilian casualties in war The first aid services would operate under the control of the Civil Defence commissioners and controllers and usually medical officers of health would discharge this duty on their behalf Trained nurses and nursing auxiliaries of the National Hospital Service Reserve would be employed in their parent hospitals until called out after an attack The doctors of the mobile first aid units would be general practitioners who would train their teams beforehand The functioning of the casualty transit centres and of the cushion and the base hospitals, with their centres for special cases was described Coördination of plans for managing and treating patients was declared to be essential since life saving and limb saving treatment alone would be practised close to the time and to the place of injury while the continuing treatment for restoration of function would be applied in base hospitals in distant areas all over the country It was conceded that the disposition of hospitals as now planned might have to be altered in the face of a threat of more powerful weapons of attack but it was considered that the principles of employment of first aid ambulance and hospital services would remain unchanged This study was arranged by a directing staff under the chairmanship of Sir Ernest Rock Carling

## Fellowships in Clinical Research

The Medical Research Council invite applications for a further series of fellowships in clinical research, tenable at centres in the United Kingdom during the academic year 1955–56 These fellowships are open to suitably qualified medical graduates who desire to prepare themselves for a career in clinical research In general, it is intended that each fellow appointed under the scheme should be given an opportunity, as part of his training for clinical research, to study methods of research in the basic subject most relevant to his particular clinical interest

The awards will be made for one year in the first instance and will be renewable annually in approved cases up to a maximum of three years in all Stipend will be at the rate of £850 per annum, rising by annual increments of £75 to £1000 per annum with superannuation provision in addition

Candidates for these fellowships, which are ordinarily restricted to British subjects resident in the United Kingdom, must be medically qualified and clinically experienced and should preferably have worked for a period in a department in which clinical research was in progress Applicants will be invited to submit their own proposals as to type and place of work, but the Council will be glad to advise successful candidates on the selection of suitable centres of study and to assist in placing them in departments or laboratories where the desired training and experience can be obtained

Applications must be sponsored in each case by the head of the appropriate department in the candidate's university or medical school, and an undertaking will be required that a suitable academic post in a clinical department will be available to the candidate in that institution on satisfactory completion of the period of study under the fellowship

Forms of application may be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S W 1, with whom applications should be lodged not later than March 1

# RRELATION OF RADIOLOGICAL AND ATHOLOGICAL CHANGES IN SOME DISEASES OF THE LUNG*

J Gough
M.D Wales
SOR OF PATHOLOGY WELSH NATIONAL SCHOOL OF MEDICINE CARDIFF

several years I have been using paper mounted s of lungs with the particular aim of comparing orbid anatomical changes with the radiological es found during life

technique of cutting sections of whole organs is old. It was used by Richard Muir in 1884 His s were mounted on glass and specimens of the que still exist in the pathology department at urgh University There are similar ones in the ment of pathology at Cambridge where they were by Professor Sims Woodhead The method was ntly not extensively employed and even when d and modified by Christeller in 1924 it did not o widely popular The preparations were first used e demonstration of changes seen by naked eye out 1924 the method was modified by T C Dodds preparation of large sections thin enough to be e for microscopy This is the method adopted ance by Cheatle and Cutler (1931) for investigation inoma of the breast

method now used (Gough and Wentworth 1948) o original features the sections are mounted on and not on glass and certain glycol derivatives ed to preserve the natural colours Staining is unnecessary, although stains can be used for special es such as the demonstration of hæmosiderin prussian blue technique These paper mounted s are now being produced in many centres in and abroad and their popularity is probably part to the simplification of the technique but to the ease and convenience of handling and paper preparations as compared with glass The s can be stored like other paper and those which kept in book form have not deteriorated during ht years since the technique was started The s can be conveniently filed with the corresponding aphs Since many sections can be obtained from k of tissue they form a convenient medium of ge between centres working on similar problems

primary object was to collect a large number of s of lungs from coalminers in order to interpret diological appearances of pneumoconiosis but I ere speak principally of other conditions which een investigated in the same way

## Mitral Stenosis

iderable interest is shown at the present time in lmonary changes associated with mitral stenosis, these lung changes undoubtedly contribute to spnœa The punctate picture due to hæmosiderin lungs is a familiar one and large sections show the distribution of the pigment which produces iological shadows More dense opacities and rather ones may be seen particularly in the lower lung Some have described the two types of shadow enting different degrees of hæmosiderosis (e.g nd Levine 1950), but anatomically it is seen that se shadows correspond with areas of ossification use of these is not known but their recognition ographs is of some importance because they may lso be mistaken for foci of tuberculosis

In some cases of mitral stenosis the lung fields show linear markings particularly in the lower parts where a series of parallel lines run in from the chest wall above the costophrenic angles Sometimes these are very sharply outlined and about a millimetre in thickness When I have asked some of my radiological colleagues what they represent, they say they are Fleischner's lines and that they represent areas of plate-like atelectasis It is true that Fleischner described such areas of atelectasis but these produce much wider and often longer areas of radio-opacity and no one more than Fleischner (1954) was puzzled by these thin lines in mitral stenosis which he was sure were not due to atelectasis although for many years he could not find an anatomical explanation It was from a study of paper mounted sections that he obtained the solution When examining some of the preparations of coalminers lungs which had been prepared in my department he was attracted by the deposition of coal in the septa between the secondary lobules, and he noted that in some cases of mitral stenosis hæmosiderin had a similar distribution and that this deposition corresponded with the position of the lines in the radiographs The large sections of lungs of coal miners are indeed very helpful in delineating some of the anatomical features in the lung In the majority of coalminers the bulk of the dust collects towards the centres of the secondary lobules especially in relation to the terminal and respiratory bronchioles (Heppleston 1953) but some of the dust accumulates in the lung septa, and in a small proportion of miners this is the main site of deposition. Likewise with hæmosiderin in most lungs it is in the form of foci in the centres of the lobules but in some it is mainly in the septa

Fleischner believed that not all the lines in mitral stenosis radiographs were due to hæmosiderin he thought that some might be due to œdema of the interlobular septa but he did not have material to show this I have however, obtained sections corresponding with radiographs taken during life to show this appearance which consists in œdema of the connective tissue of the septa together with marked distension of the lymphatics This type of line is often transient in radiographs being present during periods of cardiac failure but disappearing when there is recovery from the œdema It will be interesting to see whether the persistent lines due to hæmosiderin disappear after successful valvotomy

## Microlithiasis Alveolaris Pulmonum

The need for careful correlation of radiological and pathological findings is illustrated by the following example

In Shanks and Kerley's *Textbook of X ray Diagnosis* (1951) is a radiograph said to be of gross chronic hæmosiderosis of the lungs in a woman of 56 with mitral stenosis The lungs were intensely radio-opaque The diagnosis was based on biopsy material obtained by needle puncture. This woman has since died and an account of the post mortem findings is given by Sharp and Danino (1953) The lungs were of very unusual appearance The cause of the radio-opacity was the development of calcispherites and bone in the lung a rare condition which has been described previously in German literature under the title—microlithiasis alveolaris pulmonum (Lelcher 1949) The amount of hæmosiderin in the lungs of Sharp and Danino's case was small When sections of the lungs were mounted on paper they felt exactly like sandpaper ; the material however had not been inhaled but was endogenous and composed of calcium phosphate and calcium-carbonate The association with mitral stenosis may well have been fortuitous for other cases described have not had associated heart-disease

---

er read before the Midland Tuberculosis Society on 6 1954

In several radiological centres in this country and in the United States this condition had not apparently been encountered, but I had an interesting experience in one U S centre when I showed the radiograph at a seminar Although none of those present knew of microlithiasis alveolaris pulmonum, one of them was able to go to the archives of the department and produce a similar picture which for many years had lain there labelled " ? severe ossification in tuberculosis "

The memory of particular pictures is, of course, as great an asset to the radiologist as to the morbid histologist, and one wonders when a radiologist is puzzling over an unusual film whether he tends to think mainly of similar pictures he has seen before or whether he tends to think in terms of the underlying pathological change Paper-mounted sections filed with the corresponding radiographs may provide a useful reminder of the morbid anatomy In order to make headway in the correct interpretation of radiographs it is necessary to collect and store them so that they will be available when the pathological evidence is eventually obtained Hospital committees discuss how long radiographs should be kept, and I am disturbed at suggestions of a limit of this or that number of years In the study of a chronic disease like pneumoconiosis radiographs taken very many years ago are now proving of great value

### Emphysema

In the study of coalminers' lungs I have been interested not only in the deposition of dust but also in the emphysema that results It has been shown (Gough, James, and Wentworth 1949) that the simple postero-anterior radiograph is not a reliable means of assessing the degree of focal emphysema which occurs in coal workers, and indeed that type of radiograph appears to be unreliable in the diagnosis of emphysema of all sorts Knott and Christie (1951) have shown the inaccuracy of postero anterior radiographs in the diagnosis of emphysema

Such diagnosis can be made more accurate with radiographs taken in inspiration and expiration and both postero-anterior and lateral, but even if accuracy in deciding the presence of emphysema were obtainable in this way that is only part of the answer What sort of emphysema is it ? I have compared the lungs of people dying from the emphysema associated with chronic bronchitis with those dying in status asthmaticus I understand that radiologically chronic bronchitis and asthma do not show two distinct types of radiotranslucency, but anatomically the changes in the two are quite different Of a consecutive series of 17 cases of fatal status asthmaticus, bullous emphysema was present in only 1, and in this case there was associated severe bronchiectasis In the other cases the lungs were simply over distended just like those of a person drowned Indeed, it seems to be the most commonly accepted view that death in status asthmaticus is a form of drowning due to the tenacious mucus which the asthmatic cannot expel There was, however, no breakdown of the lung tissue to form bullæ, which is in striking contrast to the emphysema of chronic bronchitis The importance of this seems to be that the inflation of the lung in asthma is a reversible condition, whereas the destructive processes in the lung of chronic bronchitis seems to be permanent Lodge (1946) has shown that the appearance of the blood-vessels in radiographs in emphysema is different from that in asthma, but otherwise the appearance in lung fields is similar in the two conditions With chronic bronchitis and emphysema as one of the more important causes of death and morbidity, it is important that more should be learnt about it and there is need ological technique to help in distinguishing various of emphysema and to show at what stage processes take place

### Uræmic Œdema

Œdema of the lungs produces various app radiographs, and one of the more interesting central œdema which occurs in uræmia, " butterfly " appearance The histological descr the condition has been given by Doniach Recently, Herrnheiser and Hinson (1954) have gated the gross anatomy of this condition, mounted large sections They were able to show the distribution of the œdema They descri anatomical distribution of the lesion and relat the conception of the lung anatomy according each lobe is divisible into a lobar root, a cortex They found that the œdema in this limited to the medullary part These investigat those of Prichard, Daniel, and Andran (1954) the possibility of explanation of some of the findings which emerge when the circulation in is disturbed in man and in laboratory animals.

### Tuberculosis

I have not used the technique for any investigation into tuberculosis apart from coal but have prepared large sections for some centre the excision of lung is carried out The metho suitable for small segments, because expansion lung is required to obtain satisfactory results. lobe or a whole lung is removed, however, the tions have been quite satisfactory They can with the radiographs and may be of value results of a large series of cases are being Where very detailed study is required, serial several blocks of tissue may be used In this can be shown at least how much diseased and healthy tissue has been removed The section very effectively whether bronchiectasis is a the tuberculosis, and so may help in deciding cases do well and others not so well

When I first demonstrated the paper-mounted about eight years ago, doubt was expressed could do much for research, because they outmoded field of morbid anatomy I hope the given show that the researches have been measure profitable, and that the very large lung sections that we have built up has served, continue to serve, as valuable material both in path and radiological studies

# TMENT OF ACUTELY PERFORATED PEPTIC ULCERS

## DIOLOGICAL DIAGNOSIS OF SITE OF PERFORATION

H D MOORE
M.C M.B Sydney F.R C.S F.R C.S.E
OR SURGICAL TUTOR IN THE UNIVERSITY OF LEEDS

*With illustrations on plate*

purpose of this paper is to recount the experience and conclusions of one surgeon in the treatment erent methods of perforated peptic ulcers and to e a radiological technique to diagnose the site o tion.

series consists of 125 patients of whom 65 were by aspiration, 45 by simple suture of the perfora nd 15 by immediate partial gastrectomy Those by aspiration and those treated by simple suture nselected aspiration was used for all patients d to the beds of Prof P J Moir in the last three and simple suture for all patients in the beds of urgeons who regarded it as the method of choice mmediate partial gastrectomies however were a y selected group admitted to the service of Prof Chamberlain.

### Conservative Non operative or Aspiration Treatment

good accounts of the management and progress ents treated in this way have been given (e g Taylor 1940), but a few points need to be ted

dose of morphine must be large (gr $^1/_4$ for men or women intravenously) to produce comfort and spirations Only one dose is given unless the in charge of the case expressly orders otherwise on is done with a no 11 œsophageal tube and by ple three-bottle method (fig 1) A large tube is ry because the stomach contents are often glairy ink and the suction must be continuous so as to the fluid and *gas* as they collect—especially the ich these patients swallow This seems to be nt for Hermon Taylor (1951) had 2 patients, and et al. (1952) 1 who continued to leak air into itoneum and died (these workers used intermittent only) It is of course important to make sure e tube is in the dependent part of the stomach, y changing its position until it is working well using a radio-opaque tube and X ray control 5)

ys are used as a diagnostic control (the special gical diagnosis of the site of perforation is dis below) 63% of cases showed free intraperitoneal metimes a considerable amount (fig 2) without the progress in any way It has not been neces- take frequent radiographs as was done by Taylor (1951), progress is judged clinically

RESULTS

atients were treated conservatively The diag criteria are shown in table I and the results in . No case has been included where there was any about the diagnosis. The average time in hospital teen days 58 patients made an uninterrupted y; 2 were started on the conservative method re sutured some hours later; 2 had a subphrenic ; and 3 died (4 6%)

tients with early perforations had their treatment d (at nine hours and at twenty four hours) because ing pain and rigidity suggested that the ulcers ot sealed despite the patients excellent general on but at operation the perforations were found losed There was a small local collection of fluid, gas and fibrin in the region of the hole and above the right lobe of the liver but the intestines were clean and shining and there was no apparent cause for the persistent pain and rigidity The time on conservative measures did not affect their progress in any way

2 patients developed a subphrenic abscess The first, with a fifteen hour perforation formed an abscess directly which was drained he was in hospital two months The second had an eleven hour history, did very well on conservative treatment and was discharged in seventeen days It was known that he had persistent subphrenic gas and fluid but previous experience had shown that these are usually absorbed In his case, however this did not happen and he was readmitted twelve days later when the abscess was drained He was in hospital for a total of two months

Subphrenic gas often with a fluid level was present in 63% of patients It is almost always absorbed without incident even when present in large quantities (fig 2) As serial radiographs were taken in only a few cases

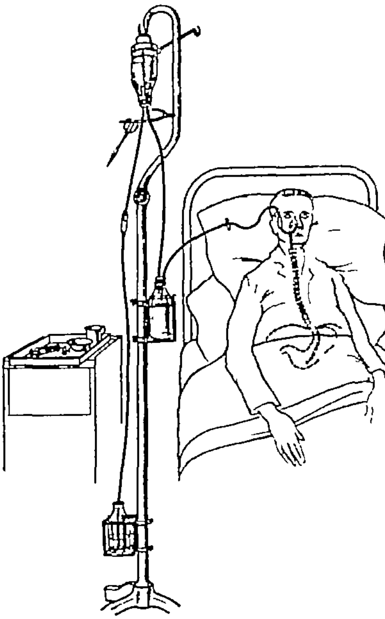

Fig 1—Three-bottle continuous-suction apparatus.

The bottles are the ordinary litre saline bottles. It is important to have the long down tube under water in the lower bottle; otherwise the water runs out. When the top bottle is empty it is simply changed with the bottom one; but it is necessary to clip the in and out tubes near the [illegible] bottle when changing; otherwise the negative pressure [illegible] the system is lost and half a bottle of water runs out [illegible] it leading to frequent changing (hence the Spen[illegible] forceps hanging on the drip stand). All glass [illegible] between the patient and the first bottle must [illegible] rest do not matter

A sterile syringe adaptor, and saline [illegible] syringe through the stomach-tube if it [illegible] and the nurses must realise that it [illegible] test drink is given and then a few [illegible] aspiration of water as well as fluid [illegible] hindered by running down the [illegible] [illegible] it is not possible to say how long the gas usually remains, but it was present, with a fluid level in 6 cases for 8, 8, 12, 14, 20, and 29 days These patients were well, with normal temperatures and leucocyte counts, and cleared without interference, but this should not lead to over confidence, as the second subphrenic abscess showed, and it would be wise to screen all perforations before discharge, to exclude an unrecognised or unresolving subphrenic collection

3 patients died (4 6%) They were men aged 43, 73, and 33, with perforations of five, six, and fifteen hours respectively, and they were alike in all being ill on admission from the peritoneal effects of the perforation—2 with a low blood pressure and rapid pulse but a short history, and 1 with a long history and beginning distension of the abdomen A 4th patient should be considered here, who is included in the results of simple suture This was a woman, aged 69, whose ulcer had p only one and a half hours previously but who was too ill for operation, because of peripheral She was treated conservatively *only* because she w She died in twenty four hours

THE BAD RISK

These 4 cases suggest that patients who are ill from the effects of the perforation—i e, with circulatory failure or with an infective ge peritonitis—will die if treated conservatively, is supported by the fact that in 56 published perforation (table III) in which the patient was to be too ill for operation, there were only 2

It seemed to me, therefore, that such patients be operated on and not treated by aspiration, following 3 cases were so treated with gratifying

e 1.—A man, aged 44 was sent to hospital with a sis of acute retention of urine because he had passed ne for twenty four hours, and had abdominal pain and apubic swelling dull to percussion. He had in point a peptic ulcer which had perforated forty-eight hours The lack of urine was due to anuria and the supra swelling which was present only when he sat up was ritoneal fluid he was gravely ill, with unrecordable pressure He was given morphine gr 1/4 put on uous gastric suction and antibiotics and given three pints of blood and two pints of dextran which brought his blood pressure to 100/70 mm. Hg Laparotomy was done three hours after admission the fluid was sucked out of the peritoneum, and the perforation was sutured He recovered and his postoperative course was not unduly difficult

Case 2 —A woman, aged 51 with an eighteen hour perforation was gravely ill with pulse rate 124 blood pressure 85/65 and a somewhat distended abdomen. She was given morphine and antibiotics, and put on continuous gastric

suction Two pints of blood were given, and the systolic blood-pressure rose to just above 100 mm Hg in about an hour Laparotomy was done, the peritoneum sucked clear, and the perforation sutured She was given two more pints of blood and two pints of dextran, and her blood-pressure, which had fallen with the anæsthesia, rose to 110 mm Hg and was maintained thereat She was discharged well a month after admission.

Case 3 —A woman, aged 36, was admitted on March 24, 1954, with three days' severe abdominal pain. She was gravely ill, with cold extremities, respirations 28 per minute, pulse rate 130–140, and systolic blood pressure below 100 mm Hg Her abdomen was tender all over, distended, and silent; a diagnosis was made of generalised peritonitis with paralytic ileus, probably arising from a perforated peptic ulcer She was given morphine and antibiotics and put on continuous gastric suction and intravenous dextran, and laparotomy was begun without waiting for the blood pressure to rise She was found to have generalised peritonitis with much free bloodstained peritoneal fluid, arising from strangulation of a loop of jejunum. This was resected, and, after a further three pints of dextran, two pints of blood, and a litre of saline solution given rapidly, her condition improved and remained satisfactory The postoperative course was singularly smooth, and she was discharged a month later

This last case is included here partly because of the mistaken diagnosis but mainly because the woman was, by the usual criteria, much too ill for operation

### COMMENT

The above results of the conservative treatment indicate that

(1) The usual course is easy and without anxiety

(2) Subphrenic gas and fluid are common (63%), but only in an occasional case are they not absorbed spontaneously Nevertheless these collections must be watched with care

(3) The patients who die are the ones who are ill on admission from the effects of the perforation These are the cases generally and widely treated by aspiration (the "forced conservative" method) and are the very ones who should *not* be treated by this method

## Simple Suture

The preoperative and postoperative treatment of these patients is the same as that of those treated by aspiration, except that less morphine is given The perforation was closed by simple transverse infolding, reinforced with an omental plug, and the peritoneal cavity was cleared of all free fluid I would add that I have never seen the peritoneum full of beer and carrots, which the opponents of the non-operative method so picturesquely describe Indeed, I have seldom been able to recognise stomach contents in the peritoneum

### RESULTS

As table II shows, 45 patients were operated on, and the average time in hospital was fifteen and a half days 40 had an uninterrupted recovery, 1 patient burst his wound, 2 developed abscesses, and 2 died (4 4%)

The "burst abdomen" was in a man, aged 53, with a seven-hour perforation There seemed to be no cause for this, and he recovered after resuture

The 2 cases of abscesses are those I have already cited to show that peritoneal toilet and suture of the perforation offer the only chance of survival where the patient is gravely ill from the peritoneal effects of the perforation Their perforations were of eighteen and forty-eight hours' standing, and both were desperately ill with gross peritonitis Their abscesses resolved without operation, but they were in hospital for forty and thirty days.

The 2 patients who died were a man aged 63, with a perforation for twenty hours, and a woman aged 69, with perforation for an hour and a half, both had long ulcer histories The man died in eight days from peritonitis The woman was treated conservatively *only* because she ught to be too ill for operation, and died within ur hours (see above)

### COMMENT

These results of simple suture of perforations that

(1) The usual course is easy and without anx

(2) From time to time complications arise which to be unavoidable, either because the cause is (e g, the burst abdomen) or because the patient late (e g, abscesses in late perforations)

(3) Some deaths seem at present to be (e g, the 8th day death from peritonitis in a stood his operation well and whose perforation sealed but who could not cope with the in the use of antibiotics), and some deaths avoided by bold measures (e g, operation in desperately ill from the peritoneal effects of the

## Partial Gastrectomy

Only patients who had perforated within and were in good condition were submitted to tomy Hence this group is highly selected

Although patients with perforated ulcers stated to be "shocked," they have, apart neglected perforation (and the occasional early normal blood-pressure and relatively slow agrees with the findings of Estes and Bennett

For gastrectomy the preoperative and post care is the same as for the patients treated by but with two differences (1) the preoperative is less, and (2) gastric suction is not used unless the patient vomits

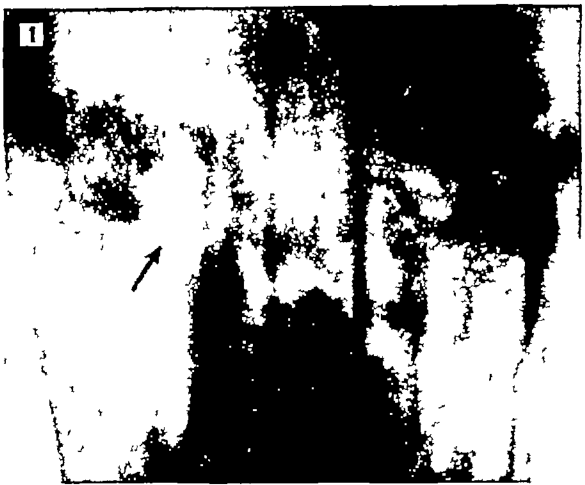
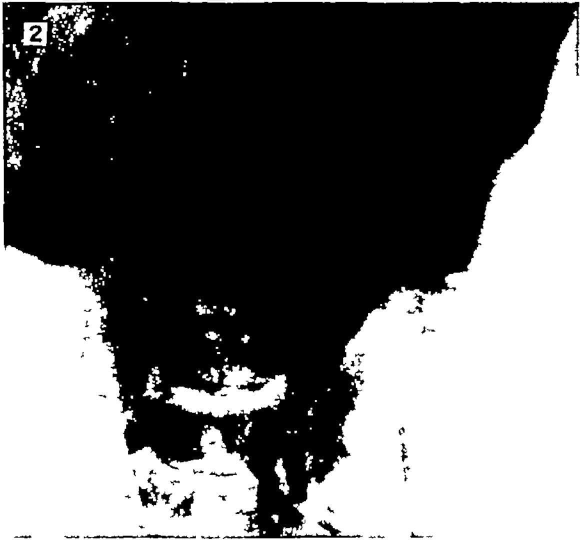
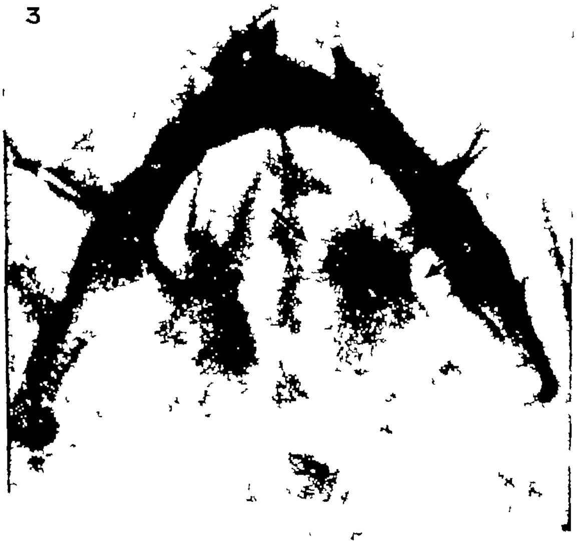
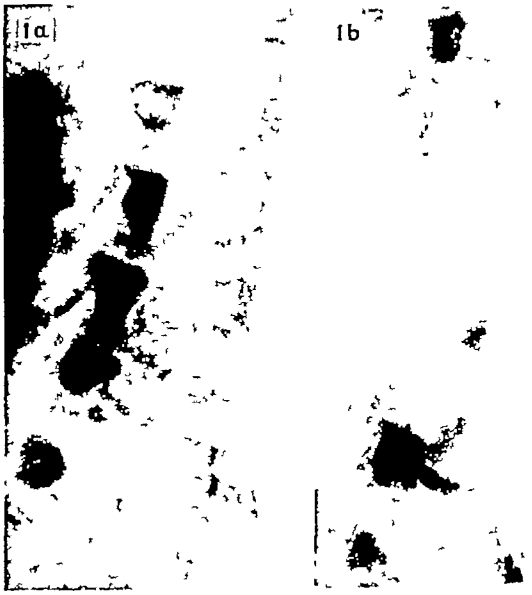
## DR HOLESH TUMOURS OF THE GLOMUS JUGULARE



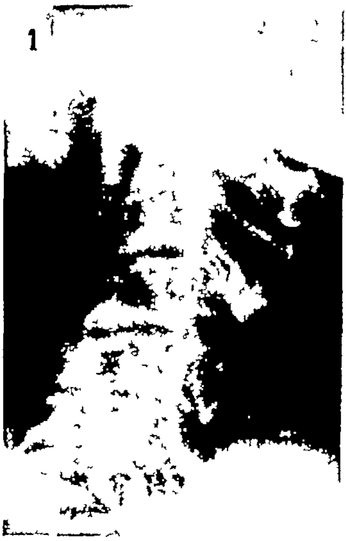


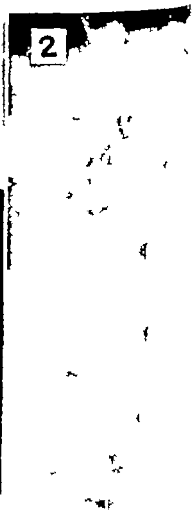


## PROFESSOR CAVE AND OTHERS OSTEO ARTHRITIS OF LUSCHKA JOI

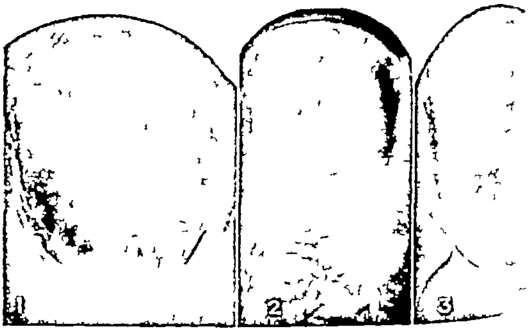


## DR CLARKE CERVICAL MYELOPAT





## DR TERRY ONYCHODERMAL BA



5 partial gastrectomies were done (table II) There e no deaths, and the striking features of these cases s the ease of the operation and the smooth post ative course (apart from 1 patient who developed umonia)

### Comparison of the Three Methods

n comparing the methods we must consider in order of ortance the number of deaths, the complications the difficulties.

*ths*

he deaths can be considered in three groups (1) re all the cases subjected to a particular method are uded without regard to the state of the patient on nission (2) the deaths which occurred with a icular method despite the fact that the patient was onably fit on admission and might have been expected urvive and (3) the deaths among patients who were n admission either from shock in the early cases or n infective peritonitis in the late

rom the present series (table II) and from the iously published cases (table IV) the following figures rge

|  | *Deaths among all admissions* |  |  | *Deaths which took place when recovery might have been expected* |  |  |
|---|---|---|---|---|---|---|
|  | *Cases* | *Deaths* |  | *Cases* | *Deaths* |  |
| -operative method | 466 | 36 | (7.7%) | 466 | 12 | (2.6%) |
| le suture | 1068 | 75 | (7.0%) | 633 | 15 | (2.4%) |
| ediate partial strectomy | 1225 | 97 | (7.9%) | 202 | 5 | (2.5%) |

he small numbers in the simple-suture and gastrec y groups where unexpected deaths are considered npared with the total numbers reported are due to fact that in many reports details of the deaths are given.

he patients who were gravely ill on admission were ally treated conservatively (the forced conserva method) Table III shows that of 50 such patients died These figures do not include the patients who e ill from cardiac failure bronchitis &c, but only se who were in poor shape from their abdominal istrophe.

he collected figures show therefore, that the mortality i whole and the mortality in reasonably fit patients do not differ appreciably whatever treatment is used but that for ill patients the conservative method is lethal. Finally, almost all published series show that the mortality of gastric ulcers whether treated conservatively or by simple suture is many times greater than that of duodenal ulcers

*Complications*

The complications can be considered as immediate and remote Table IV shows that the serious immediate complications of aspiration treatment—such as intra peritoneal abscesses—were 26 in 442 cases (5.9%) whereas in simple suture cases there were 59 in 607 cases (9.7%) In addition the 607 simple suture cases showed 105 (17.3%) lesser complications—such as wound sepsis and chest troubles—which did not occur in the con servative cases making a total of 27% No immediate complications are reported in the partial gastrectomy series but no doubt there were some although the writers emphasise the smooth postoperative course

As regards remote complications and troubles, collected series show that about half the patients who perforate will have subsequent severe symptoms (Sallick 1936, Estes and Bennett 1944 Illingworth et al. 1946 Forty 1946 Chamberlain 1951 Tandberg 1950 Lassen 1952 Gilmour 1953 Armitage 1954) It has also been shown that patients whose symptoms recur are usually those with a previous dyspeptic history (Illingworth et al 1946 Gilmour 1953), and Lowdon (1952) showed histologically that a long history is likely to indicate a chronic ulcer Finally Doll (1950) found 8.1% of 86 perforated gastric ulcers in men to be carcinomatous within three years

It therefore seems that as regards immediate compli cations simple suture is to be avoided As regards remote morbidity it seems equally clear that a long history of dyspepsia almost certainly means a recurrence of symp toms after the perforation is healed—and that a gastric ulcer is immediately and remotely dangerous

*Difficulties*

Simple suture is familiar to everyone and needs no further mention.

Aspiration is often spoken of as time-consuming and worrying It is no more time consuming than a laparo tomy but it does mean that the surgeon must be readily available in case of difficulties

Partial gastrectomy takes more time and may be impracticable for that reason

Finally if the surgeon is experienced and has a good anæsthetist he can choose his method at will If not he would be wise to avoid any operation

### Choice of Method

Patients may be divided into three groups:

(1) Those who are reasonably fit on admission—i.e. not shocked without obvious infective peritonitis and medically sound

(2) Those who are ill from the effects of the perforation

(3) Those who are ill from an associated medical condition

For patients who are reasonably fit on admission mortality is about the same for each method, and the choice of method should therefore depend on the morbidity immediate or remote As immediate compli cations are commoner with simple suture than with aspiration aspiration should be preferred to suture As between aspiration and gastrectomy aspiration is preferable for patients with a duodenal ulcer who have no history of dyspepsia or only a short history and who are therefore likely to remain symptom free after the perforation But in patients with a long ulcer history any treatment which leaves the ulcer in place will be followed by a recurrence of severe symptoms and this can be prevented only by immediate partial gastrectomy Finally gastric ulcers treated either by aspiration or by suture have a high mortality compared with duodenal

**3—Opaque onychodermal band associated with local desquamation llowing paronychia.**

ulcers, and many prove to be carcinomatous Hence immediate partial gastrectomy should be done for these also They can be diagnosed preoperatively by the radiological method described below

The patients who are ill on admission from the effects of the perforation are usually, though not always, the late perforations It seems evident that partial gastrectomy is not to be considered (Even Nuboer (1951), who does partial gastrectomy as a routine, had 3 patients whom he considered too ill for operation ) As already stated, I believe that simple suture, toilet of the peritoneum, and *vigorous* supportive measures offer the best chance of survival

Lastly there are the patients who are ill on admission from an associated medical condition such as cardiac failure or severe bronchitis I cannot produce figures to support my opinion , but it seems reasonable in these cases to avoid the added strain of an operation and anæsthetic Aspiration is therefore likely to give the best results

### CONCLUSIONS IN BRIEF

Fit patients with either a long ulcer history or a gastric ulcer should be treated by immediate partial gastrectomy

Fit patients with a very short previous history of dyspepsia, or no previous history, should be treated by aspiration

Patients ill from the effects of the perforation should be treated by simple suture, toilet of the peritoneum, and vigorous supportive measures

Patients ill from an associated medical condition should be treated by aspiration

## Radiological Diagnosis of Site and Size of Perforated Peptic Ulcer

### *Method*

On admission the patient is treated in the usual way , but, instead of plain radiography of the diaphragmatic region for gas, 30 ml of viscous diodone (' Viskiosol six ') and 30 ml of sterile water, or 40 ml of 35% diodone, is squirted down the suction-tube, or drunk Three radiographs are then taken (1) with the patient erect (this is developed and viewed to see whether the exposure is correct, which takes about 10 minutes) , a second with the patient erect , and the third (immediately after the second) with the patient supine

Gastric suction is, of course, stopped while this is being done

### *Results*

57 patients have been radiographed in this way—19 with no stomach lesion, and 38 with a perforated peptic ulcer

Of the patients with a perforation, 22 were operated on and 16 were treated by aspiration The operated cases consisted of 19 duodenal ulcers, 2 prepyloric ulcers, and 1 gastric ulcer The aspiration cases were probably all duodenal, but so far only 9 have been proved by radiography after a barium meal

The stomach was surprisingly well outlined in all cases (figs 2–8) When the patient was well and without abdominal pain (e g , in routine outpatient radiography) the diodone passed rapidly into the duodenum and jejunum (fig 6) , but of 48 cases in which there was acute abdominal pain the diodone passed out of the stomach in only 14—i e , there seemed to be a pyloric spasm in most of these cases (figs 2, 4, 5)

Among the 22 patients with perforation who were treated by operation and in whom the diagnosis was therefore confirmed, there were 19 with duodenal ulcer, and in only 6 of these had the medium passed into the duodenum In 2 of these the films had shown escape of diodone through the perforation (figs 3 and 7) In the 13 cases, in which the diodone was retained in the stomach (fig 2), the duodenal perforation could not of [illegible] demonstrated The first prepyloric ulcer had in it a tiny perforation only, and no medium into either the peritoneum or the duodenum second perforation, with a diameter of 0 5 cm., an escape of diodone and was diagnosed preop (fig 4) In the case of the gastric ulcer a large seen (fig 5)

In 7 of the 16 perforations radiographed operated on, the medium passed into the 4 of these showed the viskiosol escaping duodenal hole (fig 8) , in the other 9 the pylorus to be in spasm (fig 2)

### DISCUSSION

Diodone and viscous diodone are used because water-soluble and soon absorbed Diodone is used for urography, arteriography, &c , and is and it has been injected into the peritoneum of the pelvis in doses of 20–30 ml without harm graphy ") (Kjellberg 1942, Jefferiss and Samuel It is possible that the polyvinyl alcohol in the diodone might cause some local reaction, becau only slowly absorbed , but the amount which through the perforation is very small—much than the amounts injected into the pelvis in graphy, which causes no reactions (Bergin 1951)

This method has not yet been used in enoug one to assess its value either in perforations or cases , but a good outline of the stomach is so obtained that one should be able to diagnose ulcers with reasonable certainty Duodenal p will occasionally be demonstrated but a negative has no value A minor use is to show wh stomach is full or empty after what appeared adequate suction

## Summary

An account is given of the treatment by one of 125 acutely perforated peptic ulcers 65 by asp 45 by simple suture, and 15 by partial gastrectom

A method is described of outlining the stoma demonstrating the site of the perforation radiolog

The three methods of treatment in the present and in previously published series are comp regards mortality, morbidity, and difficulties.

In patients who are in good condition on adm

(1) The mortality is the same whatever method

(2) The immediate morbidity of simple suture higher than that of aspiration

(3) The likelihood of recurrent or persistent ulc is very great in those with a long previous hist dyspepsia

Fit patients should undergo immediate partial tomy if they have a long previous dyspeptic h but if they have had little or no previous dyspeps should be treated by aspiration

Patients who are ill on admission from the ef the perforation will die if treated by aspiration gastrectomy The ulcer should be sutured and should be given *vigorous* resuscitative treatment

Those who, on admission, are ill from an as medical condition should be treated by aspiration.

It gives me pleasure to thank the surgeons at the Infirmary at Leeds for the opportunity to treat these and to publish the results , and Prof. A S Johnston staff for facilities, help, and coöperation in the radi studies

# DIAGNOSIS OF MOURS OF THE GLOMUS JUGULARE

S Holesh

M.B Cape Town, D M.R.D  F F.R

SENIOR REGISTRAR, RADIOLOGICAL DEPARTMENT
WESTMINSTER HOSPITAL, LONDON

*With illustrations on plate*

MOURS of the glomus jugulare, once thought to be are now being reported with increasing frequency number published to date is approximately 84, but may well be more because some cases previously ded under different names are now thought to be us tumours

out half of these tumours arise in the adventitia e dome of the jugular bulb and then extend through loor of the middle ear into the tympanic cavity emainder originate from a glomus body within the oral bone Irrespective of the point of origin the ur may spread in one of two ways :

Progressive expansion in the middle ear with bulging drum which is destroyed and a granular mass then udes into the external canal.

The tumour extends medially along the petrous pyramid nscribing the labyrinth and eventually invades the l cavity with compression of central nervous structures involvement of one or more cranial nerves. These ent modes of extension account for the varying ptomatology

e tumour morphologically resembles the carotid paraganglioma and the two lesions may occur in ame patient Histologically the cells are large and gonal, with slightly eosinophilic cytoplasm and they to be uniform in size and shape They are arranged veoli or columns separated by a varying amount of na which is often very vascular Tamari et al ) consider that the adventitia of the jugular bulb is hly undifferentiated mesodermal layer and that any undergoing division here may become either a fibro a histiocyte or an endothelial cell On this basis ours arising from the glomus jugulare may vary in gross structure tendency to hæmorrhage rate of th and response to radiation therapy This also ins the confusing nomenclature

cept in children, the tumours grow very slowly and may reach an advanced stage with intracranial sion before they are identified. The duration of toms before the patient seeks attention varies from months to twenty years The length of illness may wenty to thirty years. 15–20% of cases become gnant after a long benign course Metastases have been reported in the liver, lungs, and cervical glands in a few cases

Several deaths have been recorded up to 1951 : 2 occurred after attempted removal of the tumour, 4 as a result of gross intracranial extension, and 1 following meningitis and a cerebellar abscess

The majority of patients are middle-aged females who usually present with aural symptoms A definite familial tendency has been described

## Symptoms and Signs

The commonest symptoms are chronic otorrhœa progressive deafness, tinnitus, and hæmorrhage from the affected ear especially on manipulation of a polyp which is often present If only a superficial portion of a polyp has been removed for biopsy the true diagnosis may be missed and obviously not all aural polyps are examined histologically A bruit over the mastoid area and neck is occasionally the presenting or dominant symptom

As the tumour spreads neurological disturbances occur multiple cranial palsies being characteristic The cranial nerves most frequently involved are the 7th 8th 9th 10th 11th and 12th The 5th and 6th nerves are occasionally affected Trigeminal pain or sensory disturbance may arise from local pressure without actual involvement of the nerve Ataxia and nystagmus have been described but pyramidal signs are uncommon Sensory disorders and symptoms of increased intracranial pressure are also rare

Although few present with neurological symptoms 40% of the reported cases had clinical evidence of some neurological disturbance such as hoarseness due to involvement of the vagus The earliest neurological symptoms described have been dryness or stiffness of the tongue a sensation of irritation in the pharynx dysphagia and aphonia Headaches, vomiting and failure of vision were the only manifestations in the cases recorded by Dockerty et al (1951) Hierons (1954) described a case presenting with papillœdema.

## Radiological Findings

At some stage during the disease the radiological appearances are often diagnostic but surprisingly enough there are only two radiological papers on this subject (Cova and Meda 1952 Riemenschneider et al 1953) The radiological signs are

(1) Sclerosis of the mastoid which cannot be differentiated from a chronically infected mastoid without tomography

(2) Destruction of the lower portion of the petrous pyramid the ridge remaining as a more or less intact shell (fig 1) The type of erosion peculiar to glomus tumours can only be demonstrated satisfactorily by tomography—a very simple procedure in this area.

(3) Enlargement of the jugular foramen on the affected side with perhaps a mass in the posterior nasopharynx (fig 3)

(4) On arteriography a tortuous mass of new vessels in the neck the petrotemporal region, or posterior fossa (fig. 2) (Alexander et al. (1951) think that the early blood supply of the tumour is from the external carotid artery and later also from the vertebral artery and they state that the tumours are best seen in the venous phase of the arteriogram.)

(5) Signs of raised intracranial pressure such as thinning and destruction of the clinoids when the tumour has extended widely into the middle and posterior fossa.

## Differential Diagnosis

Destruction of the base of the skull including the petrous bone may be seen in the following diseases but the erosion in glomus tumours differs in its site of origin and other features

(1) *Acoustic neuroma.*—There is less emphasis on the massive destruction of the lower portion of the petrous pyramid a the widening and erosion is chiefly of the internal audi meatus No soft tissue mass is seen in the na

(2) *Primary tumours of the nasopharynx* may erode the base of the skull but massive destruction of the entire petrous pyramid is most unusual

(3) *Chordomas*—Destruction of the dorsum sella occurs first and may extend to involve the petrous bone at a later stage The erosion of the sella is much more extensive in chordoma and there may be much calcification in the tumour

(4) *Carcinoma* of the sphenoidal sinus will show its primary destruction locally

(5) *Metastatic carcinoma* may present a similar picture to the glomus tumour

The vascularity of the glomus tumour as seen on angiograms is never a feature of these lesions, and this, coupled with the tomographic findings, clinches the diagnosis

## Illustrative Cases

The following 5 cases, seen at the Westminster Hospital, show many of the characteristic radiological findings

**Case 1**—A woman of 52 had had hoarseness for nine years when her *doctor noticed "something wrong with her tongue"* Vertigo set in eighteen months ago, and painless bleeding and purulent left otorrhœa have been present for about nine months During the past four months a squint developed with double vision on looking to the left There was paralysis of the left 5th, 6th, 7th, 8th, 10th, 11th, and 12th nerves An offensive left otorrhœa was present and a tough polyp, which bled readily on manipulation, was obstructing the left external auditory meatus There was a systolic murmur over the left mastoid extending down the neck X ray examination showed a sclerotic left mastoid with erosion of the apex of the petrous bone, the extent of the erosion was well demonstrated by tomography The left jugular foramen was enlarged A left carotid arteriogram (fig 2) showed a very vascular tumour at the base of the skull There was free communication between the carotid arteries and jugular veins The cerebral vessels were poorly filled owing to the extent of the shunt A biopsy of the aural tumour showed the typical appearances of the glomus tumour Following a course of *radiotherapy*, to a total tumour dose of 5600r, the local condition in the ear improved considerably, but *no objective change has occurred* in the neurological signs

**Case 2**—A woman of 38 had a left cortical mastoidectomy twenty years ago, followed by a radical mastoidectomy in 1941 She had no symptoms until 1948, when bleeding *occurred from the left ear Further exploration of the left* mastoid was followed by facial palsy of four months' duration

There were no further symptoms until 1951 when the left facial palsy recurred with slight hoarseness When seen in 1953 there was a left 7th nerve palsy and partial paralysis of the 5th, 6th, 9th, and 10th cranial nerves A vascular tumour was found in the left ear and biopsy confirmed the diagnosis of a glomus tuomur Tomographs showed typical destruction of the apex of the left petrous Following a course of X ray therapy (maximum tumour dose 4900r), there has been no change in the neurological signs

**Case 3**—A woman of 72 had symptoms dating back to 1939 when she had sudden weakness in the arms and legs In 1943 her tongue had become "one sided," and in 1944 she developed dysphagia and right facial weakness with a tendency to fall to the right on walking At that time there was nystagmus, partial palsy of the right 5th nerve, and complete palsy of the 7th, 8th, 9th, 10th, 11th, and 12th nerves Sensory ataxia and diminished vibration sense were also present, and a diagnosis of syringobulbia was made In 1945 new vessels were noted on the right ear drum and she complained of headaches giddiness, dysphagia, and dyspnœa Her B.P was 230/120 In 1948 she developed diplopia and because of the increase in the vascularity of the ear-drum, a hæmangioma of the tympanic membrane was diagnosed Erosion of the right petrous was first seen in 1949 and has not altered (fig 1) On her last admission a 'cherry red tumour' was seen protruding from the right ear drum which is characteristic of a glomus tumour Teleradiotherapy was started in 1945 and she has had two further courses The signs and symptoms remain unaltered

**C**  **4**—A man of 59 was admitted in 1954 with a history and pain in the right eye since September, 1947 was right proptosis and complete right 6th nerve palsy Radiographs of the skull and a right carotid arte were normal There was no abnormality in the nas or ears In 1949 hoarseness and dysphagia later slight weakness of the right arm There were of the 6th, 9th, 10th, and 11th nerves, and right deafness Tomography showed a nasopharyngeal m destruction of the right petrous and posterior clino 1950 the dysphagia had increased, and the left nerves became involved to a greater extent The sy improved after a course of radiotherapy He reasonably well and returned to work in February Sub X ray examination showed calcification above the an increase in the destruction at the base of the skull to involve the right wing of sphenoid and optic recent right carotid arteriogram showed elevation carotid siphon and straightening and stretching of the carotid in the anteroposterior view No abnormal ves seen at the site of the tumour

**Case 5**—A man of 55 was admitted to hospital with a left squint, which had been present since 19 operations on this eye in 1951 and 1952 On examina were palsies of the left 5th and 6th cranial nerves, constriction of the left visual field, and a dimini corneal reflex Deafness in the left ear had set in There was extensive destruction at the base of the erosion of the left anterior and posterior clinoids and tion above the petrous Tomography demonstrated tion of the apex of the left petrous bone as well as of the mastoid antrum A left carotid arteriogram displacement of the internal carotid and middle arteries

## Summary and Conclusions

A tumour of the glomus jugulare should be co if there is a long history of increasing unilateral a hæmorrhagic otorrhœa, or a vascular polyp in t If an apparently simple chronic otorrhœa is with unusual neurological signs, tomograph petrous bone will show characteristic findings graphy in the anteroposterior projection is m reliable than the conventional views of the petr and should be carried out in all suspicious cases arteriography is not indicated if, as so often happ diagnosis can be made on the clinical and tom findings

Of the 5 cases described here, 2 are proven histol and 1 has all the characteristic clinical and radi findings The other 2 cases (4 and 5) are probable tumours in view of the long clinical history, rel benign course, multiple cranial palsies, and charac tomographic appearances

I am indebted to Dr F M Allchin, Mr D Walker Dr Peter Kerley, and Dr S P Meadows for perm publish these cases

# CERVICAL MYELOPATHY

## A COMMON NEUROLOGICAL DISORDER

Edwin Clarke
M.D Durh and Chicago M.R C.P
URER IN NEUROLOGY POSTGRADUATE MEDICAL SCHOOL OF LONDON

*With illustrations on plate*

EGENERATION of the spine occurred in prehistoric ,als as well as in primitive man (Moodie 1923) and ges in the cervical region—now known collectively cervical spondylosis [1]* (Schmorl and Junghanns )—have been found in the ancient Egyptians fer and Riotti 1912) It is well known that cervical involvement is more common in the elderly and lendahl and Kunert (1954) report radiological evi e in 75% of persons between 50 and 75 years of age vitz (1940) and Morton (1950) found a similar inci o among cadavers and it follows that as the average of the population increases it will become even more ıent Nevertheless younger age-groups are not 'ely exempt (Hult 1954 Kuhlendahl and Kunert )

e possible clinical significance of these findings has ver only recently been recognised Involvement of pinal roots (see Frykholm 1951) is now an accepted l but the effects upon the spinal cord (Masson and e 1949 Brain et al 1952 Spillane and Lloyd 1951 Müller 1951 and others) are less well known proposed to deal only with this latter type of case and as the pathology of the condition is still ure the term cervical myelopathy —also used by (1954a)—is employed.

spite its recent publicity our knowledge of this se is still incomplete and our conceptions of it times inaccurate Thus it is often thought of as ly a surgical entity (Bucy et al 1948 Allen 1952 and Temple 1953 Semmes and Murphey 1954) ly simulating certain degenerative and frequently atable diseases of the nervous system (Jager and e 1949 Strully et al 1951 Liversedge et al 1953) e cases, however are only part of a syndrome the s of which have not yet been defined

has recently become apparent that cervical myelo y in its various degrees is a much more common der than is at the moment generally supposed and the clinical spectrum is much wider In addition ems likely that certain hitherto unexplained neuro al signs found occasionally in the elderly may be to cervical spondylosis The purpose of this paper present and evaluate cases of cervical myelopathy ved over a period of fifteen months in an attempt to tantiate these assumptions

### Classification of Material

e 32 cases of cervical spondylosis with spinal cord lications that form the basis of this report can be eniently divided into groups according to the severity e clinical picture

up I (15 cases) —All of these patients complained of le with their legs or arms or both They had the clinical gs usually associated with cervical myelopathy (Brain 1952)

up II (12 cases) —These patients had symptoms of al root irritation only but on examination evidence of compression was found

up III (3 cases) —Here neurological abnormalities were vered but no accompanying symptoms could be elicited

up IV (6 cases) —It was on occasion thought that cer myelopathy was complicating other diseases either of the nervous or other systems. 4 of the cases have already been included in groups I and II

#### GROUP I

Of the 15 patients in this group the diagnosis has been verified at necropsy in 1 (case 2) and by myelo graphy in 11 7 of the latter have been included in a review of this disorder (Clarke and Robinson) The 3 in which myelography could not be carried out because of the patients wishes or age had adequate radiological evidence of cervical spondylosis and their clinical states corresponded exactly with what is becoming accepted as characteristic of the disease

Because we have only recently become aware of cervical myelopathy as a common condition its clinical variations and in particular the early stages are not well known The cases here presented however give some indication of the degree of variation to be expected among this group of patients

The most severe type of case is represented by 4 patients They were all severely paraplegic and 3 had symptoms also in their upper extremities Of the latter the following is typical

**Case 1** —A retired postman aged 60 said that four or five years ago he had noticed cramps and aching in the calves, followed by a weakness of the right foot three years before admission to hospital Eighteen months before admission after a period of bed rest the whole right leg became weak and soon the left was similarly affected His walking deteriorated progressively until he was bedridden Two years before admission he had weakness and paræsthesiæ in the ulnar two fingers of the right hand which spread to the whole hand and arm. The same symptoms had appeared in the left hand Sphincter functions were normal and he had never had any neck symptoms.

Forty five years previously he had fallen and fractured the left clavicle but suffered no apparent sequelæ

*Examination* —He was a small poorly developed man con fined to his bed The neck was normal apart from slight painless limitation of movement in all directions except flexion Wasting was generalised in the limbs but more marked distally and coarse fasciculations could be seen in several muscles. Tone was increased in all limbs but more so in the lower extremities and more on the right side Wrist and finger extension and dorsiflexion of the foot on the right were impossible and extension of the forearm and flexion of the thigh on this side was severely affected. Weakness of a similar distribution but less severe was found on the left side The triceps jerks were absent and brisk finger flexion accompanied the biceps and supinator reflexes the finger jerks were exaggerated The abdominal reflexes were absent and those in the lower limbs much increased plantar responses were extensor Slight pain and temperature impairment could be demonstrated on the left and posterior-column modalities were decreased more on the right side and more in the legs

*Investigations* —Cervical-spine X ray : a marked lordosis centring on C6 with acute angulation forward of the spinal canal The body of C6 was wedge shaped and those of C3 C4 and C5 were distorted by gross degenerative changes (fig 1) Cerebrospinal fluid (C.S.F.): manometry performed in the usual manner showed no obstruction but with the neck in full extension a complete block could be demonstrated The fluid s contents were normal Myelogram with the neck in extension there was a complete hold up of the radio-opaque material at the level of C5-6 (fig 1) and only repeated neck flexion would allow it to pass (fig 2) There was also partial obstruction at the C4-5 and C3 4 level

*Treatment and Progress* —The patient has been provided with a plastic collar and a spring splint for the right fingers Intensive physiotherapy has produced slight improvement It is not however expected that recovery will be extensive at this stage of his disease ; surgery was not con idered po sibl

A diagnosis of ? motor neurone disease had been made elsewhere but there was clear clinical evidence of a focal cervical lesion which was located by myelograp s It is possible that the sixth cervical vertebral b damaged by the fall and the r sultant instal encouraged the excessive degenerative ch played by his occupation can only be presumptive, but for many years he had carried a postman's bag on his left shoulder His spinal cord has little or no reserve of function , for, as soon as inactivity is enforced deterioration occurs Thus, a recent pulmonary infection has undone the previous progress

---

[1] hough the primary defect is in the intervertebral disc other ctors are present and in the type of case to be described term u h as prolapsed disc should be abandoned

At the other extreme of the clinical spectrum is case 2

**Case 2** —A caretaker, aged 62, had an attack of bronchitis, to which he was subject, four months before admission to hospital On resuming work a month later, he noticed a mild weakness of the left foot so that it would drag after he had been walking for about ten minutes There were no other symptoms

*Examination* —The signs of aortic regurgitation were found and the blood pressure was 200/100 There was moderate weakness of the dorsiflexors of the left toe and foot The reflexes were increased in the left arm and leg, with an extensor plantar response on that side

*Investigations* —Cervical spine X ray severe degenerative changes especially at C5–6 and C6–7 levels C S F contents were normal and there was no block, with the neck in the neutral position

*Progress* —A month after discharge, he was readmitted in congestive cardiac failure and died the same day

*Necropsy* —Rheumatic aortic valvular disease and gross pulmonary œdema were present On the anterior wall of the cervical spinal canal and almost entirely on the left side, was an osteophytic excrescence at the disc space of C5–6 The spinal cord had been indented by it and by smaller protrusions at other levels Appropriate staining showed degeneration in the left lateral column

In patients with the more advanced disease it is not unusual to find that the first symptom was, as in this case, a weakness of one lower limb, and that over a period of months or years other extremities were involved until the full picture was produced (cf case 1)

Although many examples of cervical myelopathy similar to case 1 have been described, those with milder changes have been given less notice The following is a second instance of the latter type

**Case 3** —A male ballet-dancer, aged 39, had noticed wasting of the right hand and pain in the right shoulder for eight months Neck movements provoked the pain, and in addition he experienced paræsthesiæ in the right thumb, index, and middle fingers For a similar length of time the left leg had felt " dull " and he was less agile on it than previously

*Examination* —Lateral flexion of the neck to the right produced pain There was moderate wasting and weakness of the small muscles of the right hand and slight weakness of the triceps on that side The right triceps jerk was absent and the left knee jerk brisker than the right , the left plantar response was extensor Tactile and painful sensibility were impaired over the right thumb, index, and middle fingers

*Investigations* —Cervical spine X ray moderately severe degenerative changes at C6–7, especially on the right side C.S F (examined elsewhere) no block and contents normal Myelogram " a filling defect at the C6 level "

*Treatment and Progress* —He is still under treatment and is having intermittent neck traction and local physiotherapy to the neck and right shoulder He is relieved of the pain but the signs still persist and weakness of the left leg is unchanged.

It seems probable that this man has noticed the symptoms of cervical myelopathy early because he is observant and depends on his limbs for the execution of skilled and delicate movements Thus it is only when he is dancing that he notices a defect in the left leg , it is not noticed at other times He is the youngest patient in the whole series and it is likely that trauma has played some part in his case , his symptoms began after vigorous dancing It is unusual to find root symptoms in an upper extremity and cord symptoms in the contralateral leg More usually the root and cord symptoms are on the same side (cf cases in group II) As, however, there are often multiple cord compressing lesions in this condition, considerable variation is to be expected

[illegible] remaining 12 cases in group I are intermediate as [illegible] severity between case 1 at the one extreme and cases 2 and 3 at the other Dysphagia due t anterior osteophytes (Bauer 1953) was encoun only 1 case In 9 of the 15 cases, a diagnosis of myelopathy was made either here or elsewhere diagnosis had been propounded in each of the cases but further investigations revealed the corr Thus 3 of the patients were thought to be suffe disseminated sclerosis, 1 from syringomyelia, 1 spinal arachnoiditis, 1 from an intramedullary cord tumour, and 1 (case 1) from motor-neurone It can be stated, however, that when the picture of cervical myelopathy is adequately clinical confusion with other diseases should not

### GROUP II

The 12 patients in this group had the feat cervical root irritation but spinal cord signs (u or bilateral) could be demonstrated though th not associated with any symptoms These ca similar to those spoken of by Stookey (1940) as to " the syndrome of unilateral ventral pressure pathological lesion being a combination of root compression It should, however, be noted that th not necessarily exist at the same level, as Stooke believed

All the patients presented themselves at hosp the clinical picture of cervical root irritation, the of which have been adequately dealt with m papers (see Frykholm 1951) No estimate of incidence of these cases is possible, but during th period in which the 12 cases were observed instances of root compression without these featu encountered

The ages of the patients did not vary sig from those in group I, which is of some interest considers that cases of root compression due to losis tend to occur at an earlier age than cervical myelopathy Every patient had referable to the neck The cord signs varied but they were all mild and invariably motor sensory disorders of definite cord origin were not This is in keeping with the known susceptibility pyramidal tracts to compression, recently experimentally by Tarlov (1954) In only 1 case a contralateral extensor plantar response and is th a link with *group* I (cf case 3) 3 patients had cord signs but in the remainder they were The former included 2 cases with bilateral plantar reflexes as the only indication of cord and in 1 of these myelography confirmed the di The 3rd case is typical of this subgroup

**Case 4** —A bus driver, aged 49, had suffered pain shoulder for three years and clumsiness of the left six months He had complained of a sensation of num the left thumb for four months and the shoulder extended to this digit The lower limbs were norm

*Examination* —Neck movements to the left produ The left triceps and thigh flexors were slightly weak lations were occasionally present in the left deltoi supinator reflexes were both inverted and the fin much increased Thigh flexors were slightly weak reflexes were brisker on the left , both plantar re extensor The only sensory impairment was in the ter the left C6 root

*Investigations* —Cervical spine X rays degen changes more marked on the left C.S.F complet with neck in full extension contents normal My complete block at C4–5 with the neck in extension

*Progress* —Heat and massage to the neck and left produced gradual improvement Neck traction did any relief He now has only mild neck pain and for nine months has been able to drive his bus

In this case there is clear evidence of cord co yet there are no symptoms referable to it improved with conservative treatment but is under vation because of the chances of deterioration in yelopathy

the 9 patients with ipsilateral cord signs 6 had sed tendon jerks only in nearly every case these onfined to the lower limbs and they might or might e accompanied by extensor plantar responses and ised abdominal reflexes on that side Why hyper ia should sometimes occur without an accompanying logical plantar reflex remains unexplained In 2 slight hypertonicity existed in the ipsilateral forearm se 5 is one of them

e 5 —A housewife of 62 had experienced severe burning ooting pain in the right hand for five weeks It affected ddle finger mostly and was worse when in bed at night ion was impaired in the hand For a similar length of here had been stiffness of the neck and pain extending t into the right shoulder

*mination* —Neck movements were limited by pain was slightly increased in the right forearm but apart xaggerated tendon jerks and an extensor plantar reflex right the rest of the nervous system was normal

*stigations* —Cervical-spine X rays spondylotic changes 6 level.

*tment and Progress* —Local palliative measures have ed complete freedom from the previous symptoms for onths.

s patient was referred as a case of the carpal tunnel ome However the cord signs the neck symptoms, ative cuff test (Gilliatt and Wilson 1953) and the se to treatment directed proximally make that osis unlikely It also seems improbable that she is ing from two lesions a possibility that must be ered in some cases The finding of cord signs in of brachial neuritis" is obviously of considerable atic value

elographic evidence of the cervical lesion was only ed in 2 of the 12 cases, the other patients being in the outpatient department However the nation of cervical root irritation with cord signs, adiological evidence of spondylosis in all of them, ents a distinct syndrome

the moment the prognosis in these cases is wn but it is important to observe that although from root symptoms was achieved in most cases yelopathic signs persisted

## GROUP III

number of cases in each group does not necessarily the relative frequency of the types. Thus although are only 3 in group III these cases may be com r than any of the other types The patients, who all over 65 years of age, attended hospital for com s that were not related to the cervical spondylosis ered incidentally on X ray examination The ing is a typical example :

e 6 —An ex Army physical training instructor aged 66 ained of peculiar sensations in his knees and locking of ght elbow Five years previously he had suffered a attack of right sciatic pain

*mination* —Degenerative disease of the knee joints and osteo-arthritic changes in the right elbow accounted for mptoms However there were bilateral extensor plantar s slight impairment of joint position sense in the right e and decreased vibration sense appreciation in the parts of both lower limbs To clinical examination, the was normal

*tigations* —C rvical spine X rays gross spondylotic es maximal at C5–6 C.S.F no block with neck in exten or flexion contents normal Myelogram : moderate tation of the anterior surface of the Myodil column levels of the cervical spine but mostly at C5–6. There o block on extension A filling defect at the L4–5 level ited a prolapsed disc

*tment and Progress* —He has been treated with physio- py and is pursuing a fluctuating course closely related to f employment The abnormal signs are still present unchanged after twelve months observation

The previous attack of "sciatica" indicated a disc lesion in the lumbar region, verified by myelography That certain persons suffer from multiple disc lesions is now recognised (Brain 1954a), although some may be symptomless (Trowbridge and French 1954)

In the other 2 cases the clinical findings were much the same although in each there were reflex abnormalities in the upper as well as the lower extremities. One like case 6 had a mixture of mild motor (including slight muscle weakness) and sensory changes while the other had only motor impairment In each there was a hemiplegic distribution of the signs A lumbar puncture or a myelogram was carried out in each one of them and the findings were the same as in case 6 It is interesting to note that in this man severe cervical spondylosis prevented adequate neck extension and may therefore be protecting his spinal cord from further damage as was probably the case also in a patient belonging to group I

The cases comprising this group are included with much less certainty than any of the others However the recent study of Pallis et al (1954) and the myelographic evidence in 2 of the present cases help to confirm the existence of this clinical entity Pallis et al (1954) have investigated a group of non neurological patients over the age of 50 both clinically and radiologically They found that 60% had neurological abnormalities and all of these had cervical spondylosis As in the cases described above, the abnormal signs were mild symptomless, and either motor or sensory or both The fact that posterior osteophyte formation seen on lateral X ray examination of the cervical spine does not necessarily indicate narrowing of the spinal canal as maintained by these authors does not detract from the importance of their work. However the rôle of thoracic spondylosis (excluded in case 6 and the others) must also be considered Despite the presence of cervical spondylosis spinal-cord signs may be due to compression at a lower level

It should be noted that all the patients in group III were of limited intelligence and it is possible that they had not noticed certain disabilities that would be more readily discernible to more observant individuals

Another objection to attributing spurious neurological signs in the elderly to cervical myelopathy is the possibility of other lesions producing them. Savitsky and Madonick (1943) offer several suggestions to account for the extensor plantar reflexes in a healthy individual but the only one to be considered seriously is cerebral arteriosclerosis and associated mild cerebrovascular accidents those have been excluded as far as possible from the 3 cases of this group However this is a formidable consideration when dealing with patients over 65 At least 4 cases not included here in which this problem arose have been considered recently but in the absence of pathological studies a definite conclusion is not possible

## GROUP IV

If it is correct that cervical myelopathy is a common disorder it would not be surprising if it were found with other diseases This association has in fact been observed and group IV contains those patients in whom two pathological processes could be detected. It is convenient to consider first the occurrence of cervical myelopathy with non neurological conditions, and then the more difficult problem of two coexisting diseases of the nervous system

Cases belonging to the first type have already been included among the various groups of cervical myelopathy Thus in group I the second patient (case 2) was suffering also from aortic incompetence and died of congestive cardiac failure Another patient was admitted to hospital because of ischæmic heart-disease and was found to have the signs and symptoms of a C6-compressing lesion although she had not complained spontaneously of it Case 7 presented below is of particular interest because of the difficulty of differentiating between the two diseases

**Case 7** —A blacksmith, aged 49, was referred to Dr Russell Fraser as a case of thyrotoxic myopathy He had been losing weight for two or three months and for five weeks had noticed weakness of the legs, particularly the left one He was becoming tremulous and more excitable than usual

*Examination* —He was anxious and sweating There was generalised muscle wasting with coarse fasciculations in several groups and considerable associated weakness, more marked in the left triceps The reflexes were all abnormally brisk except the left triceps jerk which was almost absent, the plantar responses were extensor, the left being the more definite Auricular fibrillation was present, and, though the thyroid was not palpably enlarged, the patient was clinically thyrotoxic

*Investigations, Treatment, and Progress* —No C.S F block was demonstrated, but neck positioning was not employed, the protein content of the fluid was 90 mg per 100 ml Thyrotoxicosis was readily confirmed and the patient was treated with methyl thiouracil and *l* thyroxine Improvement was dramatic and when the thyrotoxic symptoms had disappeared, his only complaint was of some weakness of the left leg On re examination the only abnormalities were marked weakness of the left triceps and moderate involvement of the small muscle of the left hand the left triceps jerk was still absent and all the other reflexes were brisker than normal the plantar responses were still extensor

A manometric block with the neck in extension was now demonstrated The C S F protein content was still abnormal and X rays of the cervical spine revealed moderate changes at C5–6 and C6–7 A myelogram confirmed the block in extension the main compressing lesion being at C6–7

Now, three years after his first complaint began, his thyroid function is normal, but he still notices some weakness of his left leg

This man had severe muscle wasting associated with thyrotoxicosis and it was only after this had been treated that it was possible to evaluate the evidence of a focal cervical cord lesion No specific therapy has been directed at the latter, but he is being closely observed and deterioration will call for a further consideration of treatment

One case included in group II should also be mentioned here The patient, a man of 68, was admitted because of chronic bronchitis, and on examination was found to have severe wasting of the right shoulder girdle and biceps He stated that this had been present for about eight years He had the signs of a C5 root lesion on the right and also ipsilateral pyramidal-tract signs Neck movements especially extension, were restricted, and X rays of the cervical spine revealed marked degenerative changes at all levels In his occupation he had carried bags of coal on his shoulders

A man of 67 was suffering from diabetes mellitus but had mild pyramidal tract signs on the left side It was considered that he might be an example of diabetic myelopathy (Garland and Taverner 1953), but, in the presence of restricted neck movements, severe cervical spondylosis, and evidence elsewhere of root pain, it seems reasonable to suggest that spondylotic myelopathy may be playing a rôle in this case

It is also possible that cervical myelopathy may complicate neurological diseases, but here differentiation may be difficult or impossible Case 8 is an example of this subgroup

**Case 8** —A waitress, aged 43, for two or three years had experienced paræsthesiæ all over the right hand and to a lesser degree in the left A similar sensation, together with stiffness, had been present in the legs for about a year More recently there had been aching in the shoulders with extension to the left arm

*Examination* —She was tense and anxious but her general dition was good A coarse sustained nystagmus with l gaze to either side was found and sensation was ired over all of the left side of the face and tongue There an adductor palsy of the right vocal cord, the right side of the tongue was wasted, and active fibrillation seen The right upper limb was wasted and weak, par proximally, and the right thigh flexors were also affected All the tendon jerks were absent in the rig extremity, but in the left both the biceps and reflexes were entirely replaced by finger flexion and th and finger jerks were pathologically brisk on this side lower limbs the reflexes were increased (more so on t side) and both plantar responses were extensor P temperature sensation was impaired over the left the body and over the right shoulder, but the column modalities were affected mainly on the right principally in the hand

*Investigations* —Skull X ray no basilar Cervical spine X ray marked degenerative changes larly at the C5–6 level C S F a manometric block neck in full extension Myelogram a complete br myodil column at C5–6 level with the neck exten was therefore concluded that she had syringobul syringomyelia complicated by cervical myelopathy

*Treatment and Progress* —She was treated with therapy and a course of radiation therapy, and, althou has been little improvement in her condition, there h no deterioration over the last year

The arm reflexes indicated a focal cervical-cor and investigations showed that spondylosis was It is conceivable that patients with a cervical-cor are more likely to suffer from spondylotic c of the spinal canal because of the increased si spinal cord No attempt has been made to r compressing lesion, this will be considered if occurs The detection of this complication i im because it may be possible to relieve some sy despite the fact that the primary disease i influenced by therapy

## Discussion

Recognition of the clinical aspects of cervical losis is relatively recent One reason for the that, as Pallis et al (1954) point out, we have to believe that degenerative changes in the c spine are, like arteriosclerosis, an inevitable acc ment of the normal ageing process, as is shown tendency to describe them as "normal for the the patient" Another reason is that Schmorl associates (see Beadle 1931), when studying th vertebral disc, did not extend their investigat include the cervical spine A third is that it customary to attribute inexplicable neurological elderly persons to cerebral arteriosclerosis or t degenerative changes in the brain or spinal cord logical examination of the cord has usually been for those cases with clear evidence of a cord l information in other cases is thus incomplete

### *Incidence*

The cases included in this report were all se medical wards or in the outpatient departm general hospital It has not been found p estimate the true incidence of cervical myelop it is clear that in all its various forms it is o commonest neurological diseases encountered the same period of observation, about 40 ex uncomplicated cervical root involvement were as well as 2 cases of acute cervical cord lesion latter, 1 had a true disc prolapse and so was the cases described by Bucy et al (1948), and improvement followed operation In this was no history of neck trauma, but in the 2 frontal head injury had produced forceful hype of the neck Limb symptoms were absent but p tract signs of cervical cord origin were pres side This sequel to a head injury is well kno 1944), but it is one of the possible comp cervical spondylosis (Walshe and Ross 1936, B which was present in this patient Although t have cord lesions they have not been inclu

series because of their strict relationship to *acute*
.

### *y and Pathology*

out discussing the detailed pathological changes
cervical vertebræ (Frykholm 1951, Brain 1954a,
dahl and Kunert 1954) it is possible to suggest
pondylosis producing cervical cord compression
due to senile degenerative disc and bone changes
erefore "primary, or may be secondary ' and
ted with congenital anomalies of the cervical
ro or acute neck trauma The primary type
ts for the vast majority of cases and it seems
that chronic occupational trauma may be in part
sible in some of them (Hult 1954) Thus in 7 of
cases this possibility existed, 5 had habitually
heavy objects on their shoulders (4 in group I and
roup II) and 2 had been subjected to unusual
s (cases 3 and 6)
d secondary spondylosis—2 in group I and 1 in
II In the former the anomaly was single in one
nd involved only one lamina, but in the other
here were multiple bony lesions The group II
t had a congenital fusion of the bodies of C4 and
each of them spondylosis due to resultant mech
instability was in evidence and had produced the
sion The clinical pictures in the different types of
losis are indistinguishable and treatment is the

ætiology of the cord changes is still under dis
but the hypothesis of vascular insufficiency
l by Morton (1950) and Allen (1952) has been given
t by Mair and Druckman (1953) and Girard et al
although they do not agree on the actual mecha
This hypothesis would adequately explain the clini
lings in the present series although direct neuronal
e (Bedford et al 1952 Tarlov 1954) and arach
's (Girard et al 1954) may also play a part The
provides no direct evidence in favour of Taylor's
view that posterior as well as anterior compression
but the suggestion is a very plausible one

of the most important diagnostic features of these
s the reflexes. As was pointed out by Walshe and
(1936) the tendon jerks in the arms are of particular
ing value partial or complete inversion of the
and biceps, and a hyperactive finger jerk are
tly encountered
metry carried out with the neck in various posi
postural manometry ') is a valuable test (Kaplan
nnedy 1950) So far a 100% correlation has been
hed between the manometric findings and those
lography if the former demonstrated a block
er confirmed and localised it Furthermore in
s in group III a block was absent with both pos
anometry and myelography In figs 1 and 2 the
neck extension on the myodil column is shown
ealing with group I patients it may therefore
e be possible to dispense with myelography
al radiological and manometric findings are
This will be of value if the patient is frail or
therapy is not contemplated Experience indi
t the test is of less value in cases with evidence
r cord involvement (groups II and III) Con
of the findings of Pallis et al (1954) will
facilitate the diagnosis in the latter group
lly realised that a new diagnosis is often brought
to explain clinical mysteries, and many such
have afterwards fallen into disrepute because
soon became too popular Bearing this in mind
osis of cervical myelopathy has never been made
aution The physical signs particularly in
III and IV have been verified by more than one

### *Treatment*

The best method of managing patients with cervical myelopathy has not yet been established and difficulties are increased by an ignorance of the course of the disease, especially in groups II and III

In group I conservative measures such as a collar combined with physiotherapy and active rehabilitation should be employed first Good results were observed in 6 patients, and the progression of the disease was halted in all of them. Assessment of results is difficult however because the natural course of the disease varies considerably and is characterised by periods of arrest The degree of recovery has never been great and full return of function seems unlikely; the importance of early diagnosis and treatment is thus evident. Extensive bed rest has not been used in these cases and it seems unlikely that it has any part in therapy It may even be contraindicated for in 2 cases (case 1 is one of them) the patient's condition deteriorated when he was immobilised Neck traction is also of limited application (Brain 1954b and c) Only 1 patient having failed to respond to medical management, was operated upon and in this case though little improvement has taken place it is hoped that the advance of the disease has been arrested Surgery seems to play a less important part than some would maintain (Ricard and Masson 1951 Müller 1951 Guillaume and Caron 1954 Semmes and Murphey 1954) and a study of the whole problem of therapy is being undertaken The problem is perhaps most difficult in the early stages of the disease (case 3) for our knowledge of these cases is limited Conservative handling with close observation and consideration of laminectomy should the disease continue to progress seems to be the most satisfactory approach

Group II patients received similar treatment to those with uncomplicated root syndromes Neck traction is not necessarily contraindicated. But the patient must be observed with care because of the evidence of myelopathy and should cord signs increase a collar should be used

In group III treatment directed at the cervical spondylosis is obviously not desirable The results of further study will determine future measures

The patients in group IV present individual problems but the methods of treatment are the same

Many interesting questions arise especially in groups III and IV Much more work is needed and, as Pallis et al (1954) have suggested the neurology of old age requires revision with cervical myelopathy in mind Such studies as that of Lassek (1944) on the extensor plantar response in health and in disease must be reconsidered, and further evaluation is needed of patients with non neurological disorders who have inexplicable involvement of the nervous system There are also some complicated neurological cases which might profitably be reviewed to ascertain whether cervical spondylosis is in any way responsible for their condition

## Summary

Spinal-cord compression due to cervical spondylosis (cervical myelopathy) is a common disorder

A series of 32 cases seen during fifteen months is divided into three groups according to the severity of the clinical picture A fourth group is made up of patients with other diseases neurological or non neurological who, in addition have cervical myelopathy

This condition may explain some of the spurious signs and hitherto inexplicable neurological features discovered in the healthy and the diseased state

I am grateful to the physicians of the department of
cine Postgraduate Medical School for allowing me to p
their cases, and to Dr Hugh Davies who kin
most of the myelography

IT is currently fashionable to ascribe a significant proportion of cases of cervico brachial neuritis to a herniation or protrusion of the cervical intervertebral discs, in particular to an alleged lateral (or dorsilateral) protrusion of disc tissue into the intervertebral foramen (Frykholm 1951, Brain et al 1952, Brain 1954) The present paper directs attention to a more obvious and ubiquitous cause—namely, a deforming osteo arthritis of the joints of Luschka (neurocentral joints), a disease which constitutes, in our opinion, the commonest mechanical cause of cervical nerve-root irritation

Previous authors have described Luschka-joint osteo-arthritis and its sequelæ, without, however, gaining much notice or modifying a persistent preoccupation with disc lesions

Thus, Braun (1875) and Thoma (1931) recognised neuro central apophysitis as likely to compress the blood vessels of the cervical spinal nerves, with resultant œdema or congestion of the nerves, and Elliott (1926) knew that "spinal arthritis" could produce radicular symptoms by an osteophytic narrowing of the cervical intervertebral foramen. Gra described the characteristic radiological Luschka joint disease (his "arthrosis deformans bralis") and stressed the important relation of the apophysis to the spinal nerve Rathcke (1934) a (1937) denied the validity of Luschka's joints, but in the same situation "exostoses" which they be to differ from vertebral exostoses elsewhere Torgersen (1940) confirmed the distortion and the cervical intervertebral foramen by apophyseal and emphasised the likelihood of direct pressure phytes on the contained nerve and its vessels and the vertebral artery and nerve

Our own studies convince us that the Luschk tions are constant, normal, and necessary f the cervical spine that they are commonly th an osteo arthritis which always tends to intervertebral foramen, with or without inv its contents (figs 2b, 3b, and 4) and that the supposedly resulting from lateral herniation intervertebral disc is attributable rather to irritation, or compression of the cervical spin by an osteo arthritic Luschka joint

Our study is based upon the examination of changes in a series of 50 macerated cervical spin of known age and sex (see table), upon the dissection of a further 10 adult cervical sp particular reference to articular and disc ch upon the clinical and radiological examin unselected patients attending the surgical department of St Bartholomew's Hospital with toms or signs of cervico brachial neuritis. A of typical case-histories is given below

## Anatomy

### *The Luschka Joints*

The *Halbgelenke* of Luschka (1858) are bilater obliquely disposed paradiarthroses, situated axis and third vertebra and between each of ing cervical vertebræ By permitting the al movements of lateral flexion and rotation, neck its characteristic mobility The articular of each joint are formed by (1) the neurocentral (eminentia costarum, Luschka, processu Trolard) below and (2) the inferolateral vertebral body above The apophysis exhi an anterior non articular area (in contact with th and a posterior articular area Each apophysis, attached capsular ligament, forms the anter parietes of the cervical intervertebral foramen must restrain the disc from protrusion into the (fig 3c) The joint cavity (which is constant) medially by the periphery of the disc, later distinct capsular ligament

### *The Cervical Intervertebral Foramen*

This foramen is essentially a short canal ventromedially by the Luschka joint, dorsol the contiguous cervical articular pillars and zygapophyseal joint, and superiorly and infer relevant intervertebral (pedicular) notches ( 2a) At the medial extremity of the foramen and posterior nerve roots (the latter bearing unite to form the mixed spinal nerve, whic less in length, rapidly divides into ventral primary rami. The spinal nerve is nothing anterior and posterior nerve root fibres rearrangement into primary rami The arachnoid invests the respective nerve roo "root sleeves" of some writers) as far at medial extremity of the foramen the prote dura continues distally over the roots (th "root pouch") and the ganglion to become with the perineurium of the spinal nerve vertebral foramen (figs 1a, 2a, and 3a) is large its contained spinal nerve it is also occupi

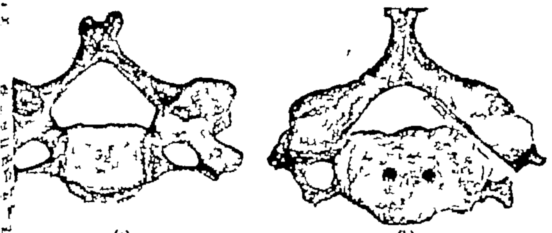
stortion of neurocentral apophyses and of intervertebral canal. (+) = mild degree of distortion + + = severe degree of distortion

t arteries an abundance of veins and much soft uid extradural fat The cervical nerve is thus accommodated and is well protected against le *compression during movement* Its *position* the foramen remains constant save for a slight l shift during flexion But it lies in intimate and able contact with the Luschka joint (fig 3c), *ation of which is invariably dorsilateralwards*—i e e medial end of the intervertebral foramen Such ation and encroachment into the foramen produces iderable abnormal angulation of the nerve root causing irritation and even compression of the root fibres and their sheaths



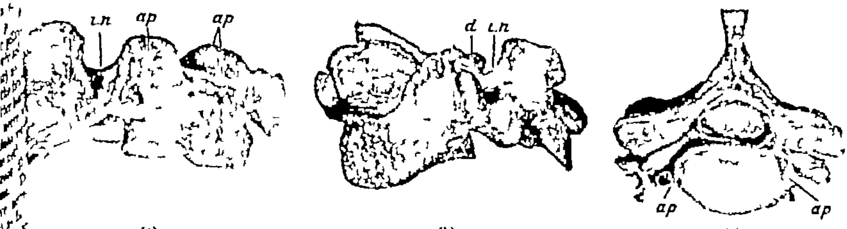
(a) (b)

(a) Normal cervical vertebra (cranial aspect) showing capacious intervertebral icular) notches; (b) cervical vertebra (cranial aspect) showing narrowing of vertebral notches by osteo-arthritis of the Luschka articulations.

## Pathology

The characteristic lesion is an 'osteo arthritic' deformity of the neurocentral joint with consequent bony encroachment upon the intervertebral foramen and a compression angulation of the contents of the foramen The articulating surfaces concerned are generally distorted (pitted and eburnated) enlarged and splayed laterally towards or into the medial end of the intervertebral canal (figs 1b 2b 3b and 4) These changes may be the only abnormality present throughout the entire cervical column as the majority of our specimens and cases show Very occasionally (in 0 8% of our cases) concomitant osteo arthritic change in the cervical zygapophyseal joints still further occludes the intervertebral foramen but it can be dismissed as a factor of any importance in distorting the foramen

*Osteophytic senile "lipping" of the caudal borders of* the cervical vertebral bodies may co-exist with Luschka joint arthritis for both are equally characteristic of the later decades of life but this is only a fortuitous asso-



(a) (b) (c)

(a) Normal cervical vertebra (right lateral aspect) showing wide intervertebral notch (*i.n.*) and height of neurocentral apophysis; (b) cervical vertebra (left lateral aspect) showing distortion (*d*) of Luschka-joint apophysis and consequent narrowing of inter- bral notch; (c) normal cervical vertebra (caudal aspect) with apophyses (*ap*) of subjacent vertebra in situ to show intimate relation ophyses to intervertebral canals and contents (dissected on left, undissected on right) and to intervertebral disc ciation, since neurocentral apophyseal osteo arthritis may occur in the absence of vertebral lipping, and the converse may also be true This lipping is more like an attempted ossification of the anterior common ligament, and we know no valid evidence that it is a cause of protrusion of the intervertebral disc

Senile shrinkage of the cervical intervertebral disc may be a cause of Luschka-joint arthritis In patients and cadavers of early middle life the disc often shows no detectable diminution in height (thickness) and radiography and dissection show that any abnormality present is confined to the neurocentral joints In later life, however, there is a varying degree of shrinkage of the disc, as part of the general vertebral changes of senile atrophy The precise cause of the osteo arthritis which deforms the neurocentral joints remains obscure, as does the cause of osteo arthritis elsewhere in the spinal column Shrinkage of the disc may be at least a predisposing or precipitating cause, for if the neurocentral arthritis results from a disturbance of the joint's normal mechanics, then shrinkage of the disc may help to produce arthritis by bringing a given neurocentral apophysis into abnormally extensive contact with the superjacent vertebral body

Nevertheless it is clear that there is no constant correlation between the degree of disc shrinkage and the distribution and severity of neurocentral osteo arthritis Thus, 5 of the 12 patients described in the accompanying case histories showed shrinkage in (usually) the lower neck, but in 2 only of these could any plausible connection be established between the shrinkage and the localisation and severity of the disease And, significantly, the adjacent zygapophyseal joints were normal

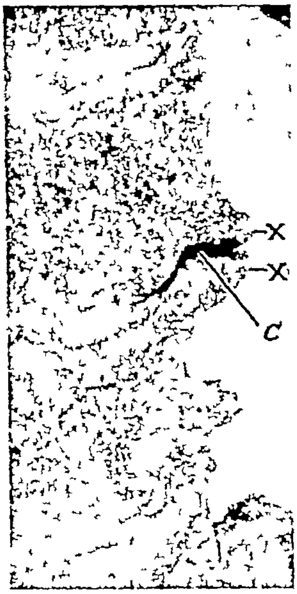


Fig 4—Frontal section through cervical spine, to show derangement of a Luschka articulation by osteophytes (C = joint cavity, XX = enlarged distorted joint surfaces)

### Radiology

In all our patients lateral oblique films of the cervical spine showed some encroachment upon the intervertebral foramina by osteophytes from the Luschka joints (fig 1b) Usually a number of foramina were narrowed, generally bilaterally, only once was a single foramen affected The precise degree of narrowing was not related directly to the severity of the disease, for symptoms result, not from compression by osteophytes, but from excessive angulation (and consequent irritation) of the spinal nerve by the osteophyte mass where the nerve enters the medial end of the intervertebral foramen This angulation and irritation of the cervical spinal nerves is comparable to that first recognised, though on a different mechanical basis, for the lumbar spinal nerves by O'Connell (1943)

Not every neck with radiological evidence of Luschka joint arthritis necessarily gives rise to symptoms On the other hand, in every patient in our series (they all had cervico brachial neuritis) radiological evidence was invariably present Radiology, therefore, can confirm suspected [illegible] lesions, but it gives no guide to the severity

Zygapophyseal osteo arthritis was also present in 1 instance This disease produces no symptoms; its occurrence merely emphasises the fact that, in the where the intervertebral foramen is very narrowing of the foramen does not, per se, symptoms A foramen may be considerably and yet there are no symptoms to produce there must be irritation of a spinal nerve by angulation over (behind) a distorted Luschka

In a third of our clinical cases the cervical disc found radiologically to have shrunk, as expected age, in the remainder the discs were depth The discs most often affected were 6/6 —that is, the discs situated where cervical is greatest

Anterior lipping of the cervical vertebral bodies ossification of the anterior common ligament, few cases, are unrelated phenomena due to age.

### Illustrative Cases

In these examples vascular lesions such as disease and vertebro costal anomalies (cervical reduced first rib) were excluded

Case 1—A woman of 64 had had three months' the radial border of the right arm, with paræsthesia 1st, 2nd, and 3rd digits pain was accentuated by cervical movement (rotation, lateral flexion) Sensibility diminished in the distribution of the median nerve right hand There was no muscle wasting, but weakness of the grip X-ray examination showed Luschka osteo arthritis was present in C5–7, and the diminution in height of disc 6/7

Case 2—A woman of 53 gave one month's history lateral cervical pain, radiating to the shoulder and clavicular region pain was persistent and accentuated ipsilateral cervical movement There was spasm of cervical muscles and consequent restriction of Cutaneous sensibility was diminished in the arm anterior primary rami of C3 and 4 No motor changes demonstrable Radiologically Luschka osteo-arthritis present in C3–6, and the disc space C6/7 was There was some ossification of the anterior common

Case 3—A woman of 49 had had several years the left index and middle fingers, with paræsthesia recently she had had pain in the left side of the neck tuated by ipsilateral cervical movement There disturbance of cutaneous sensibility The left was diminished, and the left thenar muscles were and weak Radiography showed marked Luschka arthritis in C3–7 The disc spaces were unchanged.

Case 4—A man of 42 gave a history of nine months starting in the neck and left shoulder and later along the radial border of the forearm pain was accentuated by ipsilateral cervical movement Cutaneous was diminished over the greater part of the extensor of the left forearm There was no muscle spasm or weakness in the neck or arm. Incipient Luschka arthritis was seen in C3–7 in X ray films The disc were unchanged

Case 5—A man of 50 had had one year's pain left shoulder and in the left supraclavicular region to the radial border of the upper limb and by ipsilateral cervical movement Recently pain in the cutaneous distribution of C2 and 3, and the paræsthesia of the left thumb and index finger triceps jerk was diminished. Muscle wasting and were absent Radiography showed Luschka in C4–7 The disc spaces were unchanged

Case 6—A woman of 62 had had right cervical six weeks, radiating to the shoulder and ipsilateral cervical movement She had spasm of the muscles on waking No motor or sensory changes demonstrable There was Luschka osteo arthritis The disc spaces were normal.

Case 7—A woman of 63 had had pain in the right triangle and shoulder for six weeks it was accentuated ipsilateral flexion and contralateral rotation There the neck or arm scaleni showed intermittent spasm. On X ray examina Luschka osteo arthritis was seen in C3–6 The disc s were diminished (from senile atrophy) below C1 here was much lipping of C3–7 and ossification of the or common ligament between C6 and 7

E 8 —A man of 49 had had several weeks pain radiating the lower neck over left shoulder with occasional severe bations. Residual pain was accentuated by ipsilateral al movement There were no other symptoms and no al signs. Luschka osteo-arthritis was present in C3–6 isc spaces were undiminished

E 9 —A woman of 58 gave a history of numbness ess, and pain in the right upper limb chiefly along the border of the forearm. Pain was worse at night ccentuated by contralateral cervical movement She aræsthesia and weakness of the right hand and loss of ion to pinprick in the distribution of the ulnar nerve in me hand but no cervical pain. The right triceps jerk minished Luschka osteo arthritis was visible in C4–7 o disc space 6/7 was diminished

E 10 —A woman of 51 had had ten years pain in the side of the neck radiating over the right shoulder and ing the radial border of the right forearm pain was ed by ipsilateral cervical movement She was unsuc ly treated by periodic manipulation at an osteopathic Recently pain had spread to the left side of the neck, ad not extended to the left upper limb She had hesia of the right hand The right triceps jerk was shed Luschka osteo-arthritis was seen in the radio in C4–6 and there was slight antero inferior lipping 7 The disc spaces were unchanged

E 11 —A man of 56 had had several weeks pins and in the left side of the neck to the point of the left or Luschka osteo-arthritis was visible in C3–7 and itant zygapophyseal osteo-arthritis of C3 further d narrowing of the intervertebral foramen. The disc were normal

E 12 —A woman of 45 gave a history of four years ver the right shoulder and supraclavicular region with it history of one month s pain along the radial border right forearm worse at night and on contralateral l movement She had occasional paræsthesia of the and. There were no physical signs. Radiographically a osteo arthritis was present in C3–6 The disc spaces nd 6/7 were diminished with pronounced antero lipping of C5–7 bodies

## Clinical Features

o arthritis of the Luschka joints is a common of insidious onset declaring itself most often in h and sixth decades of life (see table) but beginning frequently in the fourth As with osteo arthritis ere, it is progressive and an increasing number of ka joints become involved in the later decades and dividual distortion of each joint becomes more nced Trauma is not a cause and characteristically vical zygapophyseal joints are normal The clinical is a cervico brachial neuritis of high ' low ixed variety involving the roots of the cervical brachial plexus or of both The syndrome which ical of a mechanical irritation of the cervical roots includes in order of importance pain hesia diminished sensation to pinprick diminished muscle weakness and rarely muscle wasting

stant pain is always a symptom and is the usual of relief being sought It most commonly radiates the radial border of the arm and forearm (in tribution of C5 and 6) and it is very often associated similar kind of pain in the neck (distribution of 4) Characteristically such pain is intensified e ipsilateral (sometimes contralateral) cervical ent of lateral flexion and rotation but is unaffected flexion pure extension or rotation at the axial articulations It is often therefore worse king because of unconscious cervical movements sleep The onset of symptoms may be sudden dual and in either case subject to remissions for periods of up to six months or longer

Paræsthesia is also present in about 75% of patients and usually affects the hand (thumb index and middle fingers)

Physical signs are less obtrusive Some one third of patients have diminished sensation to pinprick or a diminished triceps reflex less than one third show weakness of the hand muscles or thenar wasting Spasm of the scaleni and deep cervical muscles may be present

Diagnosis depends on (1) the nature and distribution of the pain and/or paræsthesia (2) intensification of pain on cervical movement (generally ipsilateral) (3) the mode of onset and remissions (4) the age of the patient and (5) confirmation by lateral oblique radiographs of the neck

## Treatment

Obviously neurocentral apophysectomy of the affected joints is the only means of permanent cure but how practicable such an operation may prove when a number of Luschka joints are involved we are not competent to say Palliative therapy apart from analgesics includes long courses of short wave diathermy (which may induce a remission) and immobilisation of the cervical spine by for example a plastic or plaster collar splint (which may afford relief during acute phases) In our opinion neck traction or manipulation is valueless and is likely to aggravate symptoms

## Summary

Osteo arthritis of the cervical neurocentral (Luschka) joints is described from anatomical and clinical material with special reference to its ubiquity and age incidence

The disease is shown to be responsible for narrowing of the intervertebral foramina with consequent angulation and mechanical irritation of the cervical spinal nerve roots

We tender our appreciation to Mr D F Ellison Nash and to Mr Alan H Hunt for permission to examine patients under their care at St Bartholomew's Hospital and to Dr R A Kemp Harper for radiographic facilities in the hospital The photographs are the work of Mr A E Westwood

# THE ONYCHODERMAL BAND IN HEALTH AND DISEASE

RICHARD B TERRY
M D Lond M R C P

LATELY CONSULTANT PHYSICIAN DREADNOUGHT SEAMEN'S HOSPITAL, GREENWICH AND SENIOR REGISTRAR, ST BARTHOLOMEW'S HOSPITAL, LONDON *

*With illustrations on plate*

EACH nail bed has two clearly differentiated zones— the half moon and the larger distal pink area On close examination a third zone can often be identified in normal people it forms a barely perceptible pale narrow band, and runs transversely across the distal portion of the nail bed immediately proximal to the free edge of the nail I call it the onychodermal band and the rest of the pink area I call the main pink zone

---

* Present address The Hektoen Institute for Medical Research of the Cook County Hospital, 629 South Wood Street Chicago 12 Illinois U S A

The main pink zone may become whitened (especially in hepatic cirrhosis), giving the appearance known as "white nails" (Terry 1954a), and the half-moons may become reddened, especially in chronic heart failure in older persons (Terry 1954b) Since it seemed likely that the onychodermal bands too would be affected in some disorders, special attention was given to them in all further observations upon the nails, and changes were in fact encountered, although much less often than in the other two zones The purpose of this paper is to describe the appearance of normal and abnormal onychodermal bands, and to discuss their significance

### The Onychodermal Band in Health

In the finger nails the onychodermal band is usually 0 5–1 5 mm wide, but there are many exceptions Commonly the band is narrower and less apparent in the thumb-nail (unlike the half-moons, which are more prominent in the thumbs) The band is paler than the main pink zone, and has a slightly amber tinge and a faintly translucent quality, in Negroes, it sometimes has a trace of brown pigmentation Often a fine transverse white line may be made out at the junction of the band and the main pink zone These appearances are difficult or impossible to see unless the fingers are pointing directly at a good source of light, preferably the sun

### The Onychodermal Band in Disease

Of 2500 patients in general medical and surgical wards, 9 had onychodermal bands which were much more prominent than usual, the prominence resulting from an exaggeration of the characteristics of a normal band These abnormal bands were readily visible from a distance of at least four feet Though their whiteness did not possess the ground glass quality of the half-moons, it did preserve both the suggestion of pale amber and the translucent quality In 1 patient the bands were ivory-coloured, this patient had generalised keratosis Squeezing blood into the finger tip did not diminish the onychodermal band, indeed the contrast between the band and the congested main pink zone was accentuated

These 9 patients consisted of 5 with hepatic cirrhosis, 1 with thyrotoxicosis (fig 1), 1 with pulmonary eosinophilia, 1 with malnutrition, and 1 with keratosis

In 3 of the patients with hepatic cirrhosis there were also "white nails" This was interesting, since the juxtaposition of the abnormal onychodermal bands and the opaque main pink zones permitted the two conditions to be readily compared The opacity of the main pink zones stopped short of the abnormal onychodermal bands, and in each nail there was a narrow pink line of normal nail-bed intervening between the onychodermal band and the "white nail" (fig 2) The ground-glass opacity of the "white nails" had none of the faintly pigmented and translucent quality of the opaque bands, and this difference is apparent in monochromatic as well as polychromatic reproductions

In a recent description of "white nails" (Terry 1954a), I remarked that the whiteness usually terminated 1 0–2 0 mm. short of the distal edge of the nail bed, and I termed this narrow unaffected area the "distal pink zone" It is now apparent from further studies on "white nails" that the distal pink zone is formed by the onychodermal band

Changes in the onychodermal bands were also noticed in 2 patients with paronychia At the onset of the infection the bands were not remarkable Following resolution of the infection, there was desquamation of the skin of the terminal phalanx, and when this reached the distal portion of the nail, the bands became increasingly opaque and finally assumed a dense white colour without either pigmentation or translucency (fig 3)

onychodermal bands have been seen in both

neral skin disorders

### Anatomy

Examination of the under surface of a dry is instructive In the region of the main pink nail has a rough, unpolished appearance, whil areas corresponding to the half moon and the dermal band, the nail is smooth and shiny W rough area joins the smooth areas, small ragged may often be seen The superficial layer of the is apparently attached firmly to the nail only in th of the main pink zone Hence, when the nail is the superficial layer of the nail bed is also giving it a rough appearance, whereas in the of the onychodermal band (and of the half mo superficial layer remains attached to the nail bed

This loose attachment of the onychodermal demonstrated in everyday life by people who us nail-files to clean their nails if they are clea may separate the nail from the onychodermal Another common cause of separation of the nail band is nail-biting, which causes the onych bands to disappear Separation of this type is in contrast with the painful separation of the the main pink zone This can be demonstrated dramatically with a needle the point of the need be inserted between the nail and the onychoderm without discomfort, but, immediately the prox of the band is crossed and the main pink zone exquisite pain is experienced

The onychodermal band offers some slight to pathological processes in the main pink zone the main pink zone small hæmatomata and have been observed to have straight distal bord they were being temporarily obstructed by the dermal band As the abscess grows, it spreads *under* the onychodermal band On the other small hæmatoma grows out with the finger nail lie *superficial* to the onychodermal band, and scraped away from the under surface of the fre the nail The reason for the different behaviour abscesses and small hæmatomata is not clear

Fig 2 provides further proof of the difference the onychodermal band and the main pink zone centre of one nail there were several longitudinal the result of an injury many years previously this strip of ridges, the opacity of the "white na replaced by the normal pinkness of the main pin but the abnormal opaque onychodermal band unaltered by the ridges

The onychodermal band apparently has a blood-supply from the rest of the nail bed If th of the finger is pressed gently, there is blanching band and also of a small area of the nail bed to the band If this is repeated several times, th flushes Pressure on the centre of the dorsum of th on the other hand, causes blanching of the ma zone but not of the onychodermal band No studies have been made

### Discussion

There seem to be many reasons for thinking onychodermal band is related more to the adjac than to the nail-bed It appears to have a different supply and possibly a different blood suppl unaffected by a fault in the nail which affects th the nail bed, it is often pigmented in Negroes, involved in various local and general skin There is a thickened area of skin under the fre the nail known to dermatologists as the hypo it seems likely that the onychodermal band is a tional zone between the nail-bed and the hypon

The cases of opaque or abnormal onychoderm observed so far are too few in number to serious evaluation of their significance Since the have been observed in disorders known to be as

docrine disorders, and since well-developed bands
less marked than any in the abnormal group)
een seen in a few healthy subjects, one is tempted
gest that opaque onychodermal bands may be of
ne origin, except where the ætiology is clearly
ological However the purpose of this paper is
lly to record the characteristics of abnormal
dermal bands, in the belief that they are physical
hich should not be ignored.

## Summary

nt narrow band, the onychodermal band,' may
ntly be detected running transversely across the
portion of the nail bed in normal people
ertain diseases, a whitish opacity develops in the
odermal bands 9 examples of this condition have
bserved 5 of these were patients with hepatic
is
city of the onychodermal band constitutes a
al sign which may have clinical importance.

# A BARBITURATE ANTAGONIST

T A. B HARRIS
M.D Melb F.F.A. R C.S
ANÆSTHETIST GUY S HOSPITAL, LONDON

E months ago Shaw et al (1954) reported the
very of a barbiturate antagonist β,β methyl
glutarimide (designated NP 13):

ts mice, and rabbits NP 13 (15 mg per kg body
ht) antagonised pentobarbitone thiopentone and
tone anæsthesia, reducing the sleeping time by
and doubling the barbiturate-depressed respiration
In unanæsthetised animals NP 13 produced
ulations and/or generalised convulsions: with
of 30 mg per kg fatal convulsions occurred in
animals The intravenous injection of a barbiturate
ppropriate dose before or after the injection of
3 prevented or abolished these convulsions. During
barbitone anæsthesia in dogs NP 13 (15 mg per
restored the electro-encephalographic pattern to
al while overdose produced spikes

30 cases in which suicide had been attempted by
g barbiturates Shaw et al (1955) significantly
ened the period of coma using a mixture of NP 13
-4-diamino 5 phenylthiazole a morphine antagonist
is slightly antagonistic to barbiturates

## Observations

ofessor Shaw kindly let me have supplies of these
substances for tests during clinical anæsthesia and
e assessed their value in three types of case

e *first group* consists of fifty seven psychiatric cases
hich the patient was prepared for electrical shock
py (E C T) with thiopentone 0 5 g atropine gr $^1/_{66}$
*d* tubocurarine 30 mg The shock having been
and the attenuated clonic convulsions having
ded the subject was decurarised with neostigmine
hen given 50 mg of NP 13 and 15 mg of thiazole
venously through the same needle After the third
thiazole was omitted and the remaining 54 cases had only NP 13 In all cases, thiopentone anæsthesia was rapidly terminated, without fasciculations or convulsions The palpebral reflex was active within 30–60 seconds The patients pursed their lips and bit on their airway within 60–90 seconds. They ejected their airway in about 2 minutes and talked in an inebriated fashion within 3–4 minutes Within about 4 minutes of the injection of NP 13 the patient's state coincides with that observed 4 minutes after the completion of unprotected E C T, and it can be concluded that thiopentone anæsthesia is now completely abolished The response of the next group of subjects strengthens this conclusion

The *second group* consists of six subjects anæsthetised with thiopentone 0 5 g and atropine gr $^1/_{66}$ for orthopædic manipulations of the neck, spine and hips Here thiopentone anæsthesia is uncomplicated by the action of additional central depressants such as E C.T surgical shock, and/or surgical trauma The manipulations finished, these subjects were given 50 mg of NP 13 intravenously The palpebral reflex returned at once and they pursed their lips and ejected their airway Four of these subjects talked on the theatre table and the remaining two talked in the lift on the way back to bed

In these two groups it was noted that after the recovery produced by NP 13 the subject often lapsed into sleep again But this was natural sleep for external stimulus such as squeezing the wrist resulted in instant awakening with the startled response normally produced in a subject abruptly roused from natural sleep

The *third group* consists of ten surgical cases premedicated with hyoscine hydrobromide gr $^1/_{150}$ and Omnopon gr $^1/_3$ and anæsthetised with thiopentone 0·5 g and cyclopropane with appropriate *d* tubocurarine In these subjects surgical interference lasted from 10 to 45 minutes In two urethral dilatations lasting 10 minutes and in a cystoscopy for retrograde pyelography lasting 15 minutes recovery after 50 mg of NP 13 was rapid: the patients talked on the theatre table or in the lift on their way back to bed Six subjects for cystoscopy and fulguration of bladder papilloma lasting from 20 to 40 minutes who received 50 mg of NP 13 ejected their airway before leaving the theatre and talked within 3–7 minutes This delay in recovery compared with the second group can be attributed to the duration of cyclopropane anæsthesia After the same anæsthetic had been given for 40 minutes to a shocked patient with post prostatectomy clot retention the intravenous injection of 50 mg of NP 13 produced no observable response This can be attributed to the depressant action of cyclopropane anæsthesia and/or surgical shock

## Comments

Shaw states that NP 13 is quite innocuous and, using doses of 50 mg I have seen neither fasciculations nor any other side actions When the results in this series of seventy three cases are considered with Shaw s results in the treatment of barbiturate coma we may conclude that NP 13 is a barbiturate antagonist of real clinical worth To omit to use it in the treatment of barbiturate poisoning is to run the risk of the bronchopneumonia that is so often fatal in such cases Its use after surgical anæsthesia can be valuable but is more limited because the patient may be under the influence of central depressants other than barbiturates. In the hands of the biochemist it should prove a useful tool in investigating the nature of the affected biophase during narcosis

I wish to thank Prof F H Shaw for data and material and Dr N Cass for help and advice in carrying out the trial.

# RECURRENT MOLLUSCUM SEBACEUM

J Martin Beare
M D Belf, M.R C P
ASSISTANT PHYSICIAN, DEPARTMENT OF DERMATOLOGY, ROYAL VICTORIA HOSPITAL, BELFAST

Though molluscum sebaceum or molluscum pseudocarcinomatosum (*Lancet* 1953) is now recognised by most British dermatologists as an entity and a benign tumour, its ætiology remains obscure Cases have been published in which the growth disappeared spontaneously (Rook and Whimster 1950, Gordon 1950, Beare 1953, Halnan 1953), but I have not been able to find any published report of a molluscum sebaceum which, having been observed to disappear spontaneously, grew again on the same site, nor any reference to occasional rapid and very alarming increase in size of the tumour after surgical interference These two features may be of value in any discussion on the ætiology of molluscum sebaceum and certainly will have to be explained by any hypothesis put forward to explain the causation The following case-reports may therefore be of interest

## Case-reports

**Case 1** —A woman, aged 62, attended the skin department of the Royal Victoria Hospital, Belfast, on April 1, 1953, with a typical molluscum sebaceum about 1 cm in diameter on the back of her left hand (fig 1*a*) The lesion had been present for six weeks The patient had no complaint other than that occasionally this nodule was painful when injured It was decide to leave this tumour untreated, and photographs showing its spontaneous disappearance were taken The clinical diagnosis was so obvious that a biopsy was not regarded as essential The patient was most coöperative and attended the department regularly

*Progress* —On April 15, 1953 (eighth week), there was very little change, except that the central keratin plug was a little larger (fig 1*b*) On May 27, 1953 (fourteenth week), the keratin plug was much larger and lifted off readily, and the peripheral part of the lesion showed early resolution (fig 1*c*) On June 30, 1953 (nineteenth week), the tumour was still (fig 1*d*) On Sept 3, 1953 (twenty-eighth week) it had completely disappeared but had left a superficial scar (fig 1*e*)

*Recurrence* —At this stage it was thought that no trouble need be expected, but on Sept 30, 1953, a papule $^{1}/_{8}$ in in diameter was noted at the proximal of the scarred area, and on Oct 21, 1953, this pap become slightly larger and was by now another molluscum sebaceum (fig 1*f*) It was considered to leave this alone, and the lesion was removed surgical excision, thereby supplying a good biopsy Histological examination confirmed the clinical of molluscum sebaceum and showed large amou formed keratin and pseudo epitheliomatous (fig 2)

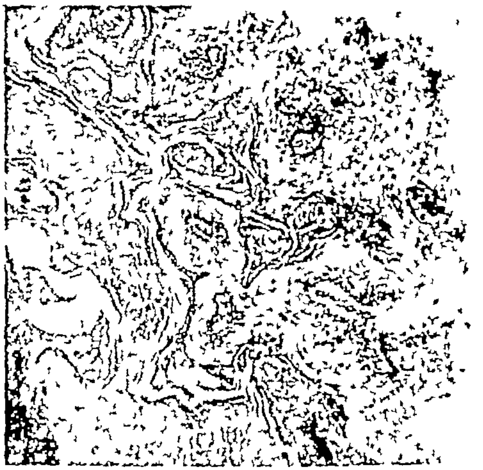

Fig 2—Biopsy specimen of recurrent molluscum sebaceum showing keratin and pseudo-epitheliomatous hyperplasia

**Case 2** —A man, aged 69, attended the skin the Royal Victoria Hospital, Jan 27, 1954, with a typical sebaceum of two months' duration cheek (fig 3*a*) This was removed planing off the top of the tumour scalpel and controlling hæmorrhage cautery

*Recurrence* —On Feb 16 a lesion as large as the original one was present same site This was at first left alone, March 2 it was larger than the orig on March 16 was relatively enormous, being 3 cm in diameter The ly glands were not enlarged However, clinical point of view a diagnosis of m sebaceum seemed correct, and the his appearance of the original fragment r on Jan. 27 was characteristic of mo sebaceum

*Treatment* —The recurring lesion treated with X rays 1500r, 90 kV, (inherent filtration 0 5 mm alumin March 16 The lesion was a little sm April 2, and the central keratin plug on April 7 Thenceforward rapid r took place, and by May 26 no abn was apparent other than some sl scarring (fig 3*c*) The patient remain

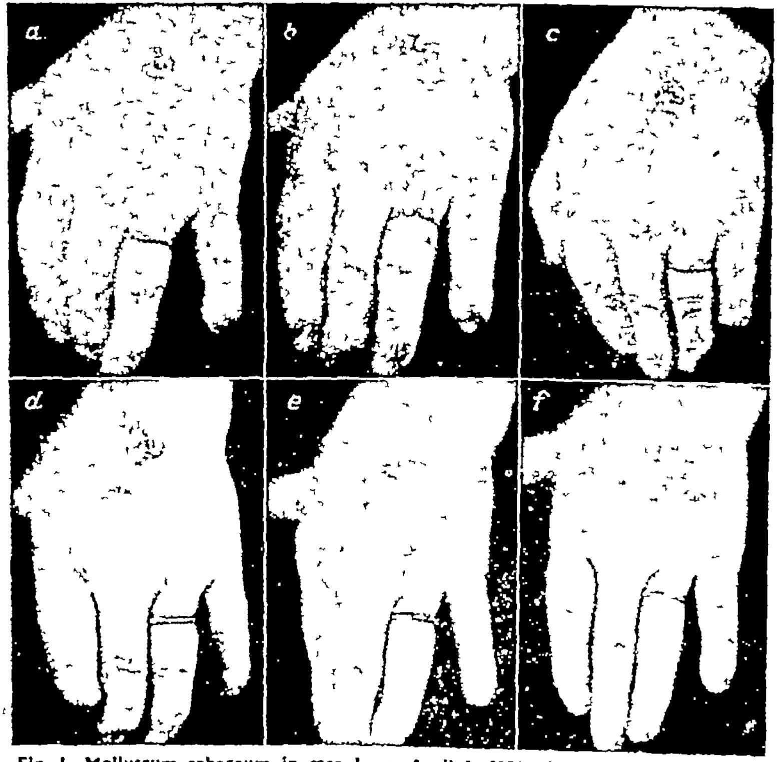

Fig 1—Molluscum sebaceum in case 1 *a* April 1, 1953 *b* April 15 *c* May 27 *d* July 30 *e*, Sept. 3 *f* Oct. 21

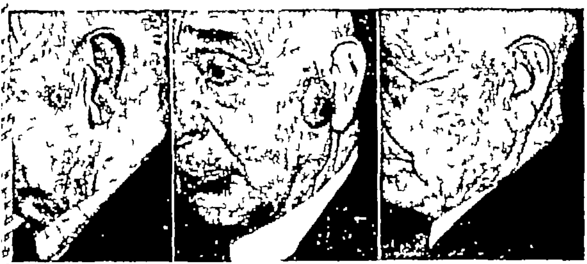
## DISCUSSION

Since January, 1940, 122 of tumours have been studied, includ 76 seen up to February, 1952, and reported (Beare 1953) The treatment has been planing off the t getting a biopsy specimen, follow application of the cautery This trea seems to be satisfactory Apart

, in which an alarming state of affairs developed
urgical intervention of this type, and case 1, which
ot treated at all there have been 3 other recurrences
present series (1) a lesion, as big as the original,
ed eight weeks after treatment and was removed
e same method this time satisfactorily (2) a
ence was noted three months after curettage
y, and X rays 1200r 00 kV 5 mA (inherent
on 0 5 mm. aluminium) and was satisfactorily
ed by curettage and (3) a small nodule recurred
nth after simple planing and cautery and was
ctorily removed by the same method

ncy (1954) showed that these tumours can be
d with a relatively low dose of X rays—1500–
The important point now firmly established,
t the lesion usually responds to simple therapy,
hat the therapeutic techniques used for the treat-
of malignant skin lesions, whether surgical or radio
are quite unnecessary and indeed undesirable
inted out in *The Lancet* (1954) It is no less
lling to save a patient with a benign lesion from the
nforts anxieties and dangers of treatment for

rapid increase in size of the lesion in case 2 after
al interference was unique in the present series but
bled the state of affairs which occasionally follows
nge of warts, especially plantar warts, when after
al removal of a small lesion an enormous verrucous



a b c

Fig 3—Molluscum sebaceum in case 2: a Jan. 27 1954; b March 16; c, May 26.

levelops. Most of those who have treated many
r warts have probably seen this unfortunate and
rassing complication Occasionally the mass which
s is too large to allow of a further attempt at
al removal Since plantar warts are a virus
on it is tempting to regard molluscum sebaceum
a virus infection Case 1 however would be more
lt to explain on a basis of virus infection and
ts to reproduce the condition experimentally by
ng crude filtrates of the tumour have so far failed
1953)

### Summary

molluscum sebaceum disappeared spontaneously
as followed almost immediately by a recurrence
same site

ther molluscum sebaceum grew to an enormous
ter it had been partly removed surgically

# TREATMENT OF LEAD POISONING
## WITH CALCIUM DISODIUM VERSENATE

H McC Giles
M B Camb M.R C.P D C.H
SENIOR REGISTRAR

O J Moore
M B Camb
HOUSE PHYSICIAN

DEPARTMENT OF PÆDIATRICS

Bessie M. Still
Ph.D., B.Sc Lond. A.R.I C
ASSISTANT LECTURER IN CHEMICAL PATHOLOGY

ST MARY'S HOSPITAL, LONDON

The use of the calcium complex of ethylenediamine tetra acetic acid (calcium disodium versenate) in the treatment of lead poisoning was first reported in 1952 (Bessman et al ) Its efficacy has been confirmed in several subsequent reports (Belknap 1952 Rubin et al 1953 Karpinski et al 1953 Bessman et al 1954, Byers and Maloof 1954, Hardy et al 1954) all relating to intravenous therapy Sidbury et al (1953) and Bradley and Powell (1954) have recently used an oral preparation with benefit in cases of chronic poisoning All the reports are from the United States.

### Case-report

A boy aged 2½ was admitted to hospital on Sept 6 1954 He had been chewing and sucking objects all his life and for 6 months had been gnawing lead-covered telephone wires on the balcony of his home 3 weeks before admission he began to have morning vomiting and to be unwontedly irritable 2 days before admission he became listless vomited through the day, and complained of abdominal pain. The drowsiness increased and he apparently began to have some difficulty with micturition but otherwise his symptoms remained unchanged until his admission.

*Examination*

On admission the child was pale ill drowsy and lay curled up on his side resenting any interference There were no other abnormal clinical signs.

2 days after admission immediately before the first infusion of calcium disodium versenate a generalised convulsion took place which lasted an hour

*Investigations*

In addition to the investigations recorded in the accompanying table and figure the leucocyte-count was 15 000 per c.mm (3 late normoblasts per 100 leucocytes) the serum bilirubin 0·8 mg per 100 ml., and Ehrlich's urinary urobilinogen test was positive at 1 in 20 dilution The cerebrospinal fluid (C.S.F ) contained 3 leucocytes per c.mm Radiographs of the long bones showed dense bands at the metaphyses consistent with heavy metal poisoning An electro-encephalogram showed activity at 8 cycles per sec and, during sleep irregular activity of moderately high amplitude at 3–5 cycles per sec Lead poisoning was diag

**Effect of calcium disodium versenate and ammonium chloride on blood-lead levels and on urinary lead and coproporphyrin excretion**

nosed but treatment was withheld until a 24 hour urine sample had been collected for estimation of lead (see figure)

*Treatment*

Calcium disodium versenate was given intravenously at 12 hourly intervals (0 5 g in 200 ml of 0 18% sodium chloride in 4 3% dextrose), each infusion lasting some 2 hours Three 5 day courses of versenate were given, with intervening rest periods of 6 and 9 days

*Progress*

There were no further convulsions or vomiting after the first infusion of versenate The volume of urine increased rapidly from 194 ml to 1130 ml per 24 hours The patient's mental state improved steadily, and after 3 days he was bright and alert, he subsequently showed no further clinical evidence of lead poisoning

The lead levels in blood and urine, together with other serial investigations, are shown in the figure and table Except for a few samples obtained during or immediately after a course of versenate, his urine regularly gave a green reduction of Benedict's solution, albumin and casts were not found On Sept 15, liver function tests showed total protein 6 6 g per 100 ml (albumin 5 3 g, globulin 1 3 g), thymol turbidity 1 unit, alkaline phosphatase 12 6 King Armstrong units On Oct 1, fasting blood sugar was 100 mg per 100 ml On Oct 4, radiographs showed no change in the metaphyseal bands An electrocardiogram on Oct 14 was normal

He was discharged from hospital on Oct 17 When seen again on Oct 21, he was clinically well and his mental state seemed normal His urine continued to reduce Benedict's solution, and the coproporphyrin test was positive, the blood lead had risen to 85 µg per 100 ml His leucocyte count was 10,000 per c mm and platelets 150,000 per c mm, prothrombin time was 80% normal, bleeding time (Duke) 3 minutes, and clotting time (Lee and White) 5 minutes, serum calcium was 10 6 mg per 100 ml, and serum phosphorus 4 1 mg per 100 ml

## Methods

Urine was collected through a length of Paul's tubing strapped to the penis and leading to a Winchester flask previously treated with lead free nitric acid

*Coproporphyrin*

Urinary coproporphyrin was tested for by taking 5 ml of fresh urine in a test tube and adding 2–3 drops hydrogen peroxide, 5 drops glacial acetic acid, and 1–2 ml ether, after 10 minutes the other layer was inspected under a Wood's lamp for the characteristic reddish pink fluorescence

*Lead*

Determinations of the lead content of 5 ml blood and 20–50 ml urine were carried out as recommended by the Lead Panel (1954) "Wet ash" digestion was followed by extraction of dithizonate without using dithiocarbamate The the lead complex was measured on the Hilger ter, using the green filter (no 604, 520 mµ) This

technique, which varies only in detail from that Karpinski et al (1953), determines the total lead, combination with versenate and free In the first treatment the lead in the urine samples was unfor estimated by a method in which the lead is separated urine by co precipitation with calcium oxalate (Bl Allcroft 1950) before wet ashing At normal pH versenate did not co precipitate, and therefore only lead was determined (it was, however, observed th urine was strongly acidified—e g, with 10 ml. hydrochloric acid per litre—the lead versenate dissociated and all the lead was co precipitated calcium oxalate) After the first period of versenate both the free and total lead in the urine were de

For 2 to 3 days after stopping versenate, the remained at a higher level than the free lead, which that the excretion of lead-versenate complex contin that period this agrees with the observations of H (1954) During the second period of treatment the which in the preceding rest period had not fallen bel per day, diminished to 0 05 mg per day, although lead had risen at this time to between 3 and 4 mg.

## Discussion

Calcium disodium versenate is the calcium of ethylenediamine tetra-acetic acid (E D T A) is a chelating agent—i e, a substance capable of multivalent metallic ions so as to cause their removal from solution The stability of comp formed varies with the metal concerned, and forming a stronger complex can replace one weaker complex Thus lead displaces calcium calcium disodium complex, which for this reason in the treatment of lead poisoning The calcium must be used because E D T A alone would comb calcium in the plasma so rapidly as to cause hypo tetany and death (Popovici et al 1950) Exp on animals (Bauer et al 1952) have shown that disodium versenate causes no serious rea patient of Belknap's (1952) showed transient marrow depression, Bradley (1954) described changes in the electrocardiogram, and one of (1953) patients had abdominal pain and diarr high oral dosage, but no other definite toxic eff been reported in man

*Dosage*

Dosage has been somewhat empirical, but the mendations of Foreman et al (1953), based on animals, are as follows the drug should be give venously, and no faster than 0 5 g per 30 lb body per hour, the daily dose should not exceed 1 g p body-weight nor the weekly dose 5 g per 30 lb weight, and courses should be limited to 7 5 30 lb body weight given over 10 days, with 7- periods between courses Maison (1953) suggests drug should not be injected in a concentration than 3% Bessman et al (1954) give 0 5 g of 8 hourly for 5 days with 3 day rest periods. It is that such doses are unnecessarily large Su of calcium disodium versenate binds 1 mM 1 g (the recommended daily dose for a child could bind 553 mg of lead The maximum urinary lead excretion is, however, in all report that of Hardy et al [1954], which concerns adult 4 mg, this is likely to represent almost the versenate excretion, since it has been shown up to 99% of an intravenous dose of E D T A able from the urine (Foreman et al 1953) Cle a minute proportion of the lead-binding capacity administered calcium disodium versenate is util the fact that versenate has to compete for lead binding agents, such as the sulphydryl groups of (Bessman et al 1954), does not entirely rob this of its validity Moreover, figures quoted in other relating to patients who were given various versenate do not suggest that either blood- urinary excretions were increased by higher do *onse*

ur patient responded to treatment in much the same as the other reported cases Vomiting and convul ceased from the time that versenate was started the child rapidly became less irritable and more alert gradual disappearance of coproporphyrin from his , and of stippled cells from the blood the rise in oglobin, and the fall in blood urea and in o s.r in are recorded in the accompanying table and e Urobilinogen was present only in the first sample ine *glycosuria has persisted up to the most recent* Although as already mentioned lead estimations ig the first course of versenate were made by a od which does not assay lead complexed with A., the excretion figures for the second and third es *show clearly that the urinary output of lead* greatly increased by giving versenate Probably epresents an increase in total lead output, since the mum fæcal excretion observed by Aub et al (1925) in nts with lead poisoning was only 1 86 mg over a period, even if excretion by this route were letely suppressed during versenate therapy it would early cancel out the increase in urinary excretion

figures for blood lead levels show a steady fall unlike given in previous reports, which often showed a striking uring versenate therapy This may be related to the noted in experiments on animals that 60–90% of an enous dose of versenate is excreted within 6 hours man et al 1953) Blood samples were (with one excep- obtained a minimum of 9 hours after each versenate on If the previous workers obtained their samples during rtly after an infusion their results might well be differ but none of the published reports gives the information s point.

ere is ample evidence that calcium disodium nate effectively relieves the symptoms of acute poisoning moreover comparison of the amount of eliminated during treatment with the fall in blood levels suggests that stored lead must be removed nly from the blood but also from the tissues Much r quantities remain in the skeleton and elsewhere even after versenate treatment mobilisation may place and acute poisoning recur (e.g , in the course of ection or from other metabolic stress) It therefore d logical to try to increase the excretion of lead g versenate treatment by any available means as shown in the figure ammonium chloride was nistered on two occasions No effect was observed inary lead excretion ; this may have been because ate acidosis was not obtained—the blood pH fell o 7 38 and the plasma bicarbonate to 23 2 m eq tre (Oct 6)—or because the patient was not on a alcium diet (Aub 1935) or because ammonium de was not given for long enough The possibility ch controlled elimination of lead warrants further loration

### Summary

treatment with calcium disodium versenate of lead poisoning in a child of 2½ is described No effects from the versenate were observed Problems sage and the interpretation of changes in blood rinary lead content are discussed

ministration of ammonium chloride during versenate nent did not increase the urinary excretion of lead

work was undertaken at the suggestion of Dr R rood The calcium disodium versenate was supplied by Laboratories, Loughborough

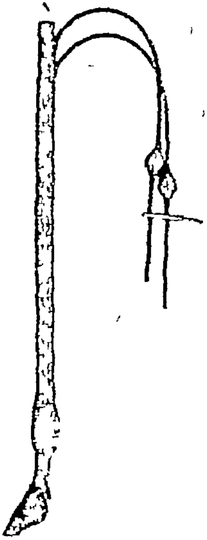
# New Inventions

## A NEW RIGHT ENDOBRONCHIAL TUBE

WE have designed an endobronchial tube for right-lung anæsthesia. This instrument permits ventilation of *all* the lobes of the right lung and facilitates transection and closure of the left main bronchus or of the tracheal wall

The tube (see figure) is made of rubber and has a cross section similar to a size 8 "streamline" Magill tube. The lower 4 cm is angulated *approximately 20* On this angulated portion of the tube is a slot 2 cm. long and 2 mm. wide. An inflatable cuff is attached to the margins of this aperture and surrounds the remainder of this portion of the tube A stiff rubber hook, similar to that on a Carlens tube,[1] projects from the angle of the tube opposite and 1 cm. above the slot. A second inflatable cuff, similar to that on a standard endotracheal tube, has its lower margin 2 cm. above the hook. The inflating tube of the lower cuff runs in the wall of the main tube, and that of the intratracheal cuff runs on the surface of the main tube



The tube is passed through the larynx under direct vision and advanced blindly down the trachea until the hook is felt to impinge on the carina The angled end of the tube will now lie in the right main bronchus. Inflation of the intratracheal cuff will help to stabilise the instrument and hold it in position When the lower cuff is inflated it will push the slot over the right upper lobe bronchial orifice and occlude the lumen of the right main bronchus. Now closed ventilation of the whole of the right lung *may be maintained When the left chest has been* opened, the intratracheal cuff can be temporarily deflated to allow the left lung to collapse to the extent required *After closure of the left bronchial stump both cuffs may* be deflated and while aspiration is performed through the tube the latter is withdrawn into the trachea The upper cuff is now reinflated to allow the adequacy of the bronchial closure to be tested

Rarely the right upper-lobe bronchus arises from the trachea In this case the tube cannot be used Therefore all patients should be bronchoscoped to determine the nature of the bronchial anatomy

The Gordon-Green Endobronchial Tube is obtainable from Messrs. A Charles King 27 Devonshire Street W 1

# Reviews of Books

## Into General Practice

*A Guide for the Beginner and Others* J G THWAITES, M B London Heinemann Medical Books 1954 Pp 223 12*s* 6*d*

THE aspirant to general practice could fill a bedside shelf with guide-books, some of which tend to duplicate each other, but Dr Thwaites in this non-clinical guide-book has made a distinctive and valuable contribution to the subject He aims at telling the reader what general practice is like at present, what are its rewards and disappointments, duties, opportunities, limitations, pitfalls, and dangers, how to enter (or try to enter) it, and what to do or not to do when in Though he by no means eschews detail, he is concerned at bottom with principles His guide is obviously the fruit of experience and thought, and it may be commended to all who either wish or ought to know more than they do about general practice and general practitioners in this country today

## Amputations

LEON GILLIS, M B E, M B Witw'srand, M CH ORTH Lpool, F R C S, consultant orthopædic surgeon, Queen Mary's (Roehampton) Hospital, London London Heinemann Medical Books 1954 Pp 431 84*s*

ORTHOPÆDICS already covers a larger field than "general surgery," and is subdividing into specialties Mr Gillis intends to produce a companion volume on artificial limbs and thus to cover all the problems which arise in amputees and those about to lose a limb He writes with the authority which his experience at Roehampton warrants, and this is certainly the most comprehensive work on amputations yet produced in this country

By its very scope it has involved the author in some difficulties He has included descriptions of conditions which may eventually give rise to the need for amputation, and his survey of the pathology and clinical course of so many diverse diseases is superficial and sometimes unsatisfactory Where he restricts himself to the immediate problems of amputations and amputees he is full of wisdom which will help every orthopædic surgeon

Particularly valuable are the chapters on amputations in children finger amputations, phantom limbs, and other complications which can affect the stump He has a good opinion of Syme's amputation when properly done, and recommends disarticulation at the knee as an excellent operation where indicated in children He agrees with general opinion in decrying guillotine amputations in emergency surgery, but he only refers in passing to the procedure of fashioning flaps and retaining them in position by a single suture over a generous gauze pack which was found so valuable by forward surgeons in the 1939–45 war

The book has many well reproduced illustrations, though some of the radiographs are too small to show the point at issue Doubtless many of the references were inserted to make the list complete, but a bibliography of over fifty pages seems excessive in a book of this size

This helpful book is to be highly commended to all who have to make the onerous decisions which amputation surgery involves

## Roentgen-Diagnostics

Vol IV *Gastrointestinal Tract, Gynecology, Urology* H R SCHINZ, W E BAENSCH, E FRIEDL, and E UEHLINGER Translator and editor JAMES T CASE London Heinemann Medical Books 1954 Pp 4029 £15

THIS is the fourth and final volume of this ponderous work on X-ray diagnosis Like its predecessors it has beautiful illustrations and a patchy, and at times uncritical, text

In general, the common disorders which face the practising radiologist and the student are all extremely well and elaborately described and in this particular volume the accounts of the biliary and renal tracts are first-class It is depressing however to find pages on gastric tone and gastritis, ve[illegible] ively little on hiatus hernia The appearances [illegible] mer Vinson syndrome and cricopharyngeus [illegible]

spasm get only a paragraph, while Evans's view of [illegible] arrhythmia as a cause of cardiac pain is accepted [illegible] question In places the clinical and pathological [illegible] not properly correlated with the X ray findings [illegible] the student to think when he reads that the [illegible] involved in 90% of cases of pulmonary tubercul[illegible] frequently in the early stages ?

The translation is a literal one and in places [illegible] from the verbosity of the original language The volumes cost £60 Much will stand the test of [illegible] much will be obsolete in ten years The trouble [illegible] an expensive production is that its cost almost [illegible] another edition within a reasonable period

## A History of Medicine

Vols I and II RALPH H. MAJOR M D, pr[illegible] medicine and of the history of medicine, Univ[illegible] Kansas Springfield, Ill Charles C Thomas [illegible] Blackwell Scientific Publications 1954 Pp [illegible]

THOSE who know Professor Major's *Classic D[illegible] of Disease* have been looking forward to the pu[illegible] of his history of medicine We are now more th[illegible] in his debt, for it is a splendid piece of work It [illegible] primarily to interest medical students and doctors [illegible] history of their profession, "which despite atta[illegible] abuse, despite quacks and charlatans, and in spi[illegible] own mistakes, has proved itself more enduring th[illegible] of the civilisations which gave birth to it"

Professor Major describes the development of th[illegible] art from prehistoric times to the middle of the 20th [illegible] from the days of the *Pithecanthropus erectus* of [illegible] lived some 500,000 years ago, down to the dis[illegible] cortisone His method is to describe the main [illegible] medical history in a connected narrative, and add [illegible] of each chapter a biographical section where the [illegible] find details of the lives of those whose achievemen[illegible] discussed The descriptions of developments in diff[illegible] ical schools during limited periods are particularl[illegible] for example, there are admirable sections on the [illegible] the Irish schools and the Great Men of Guy's during [illegible] half of the 19th century The four hundred (often [illegible] illustrations add greatly to the interest of the book and [illegible] many points which would be obscure from a descrip[illegible] Some are from photographs taken by the author [illegible] various parts of the world

Professor Major's interest in medical histo[illegible] from his student days when he came under the [illegible] Osler He shows himself a born writer, and his [illegible] one of the best and quite the most readable of the [illegible] histories of medicine It is a pity that its pr[illegible] prevent it from reaching the hands of most of our stu[illegible] but it is worth every penny Contrary to the [illegible] expectation it will also appeal to medical histori[illegible]

## Cervical Spine and Nervous System

HE *neurological manifestations* of changes in the ical spine have received much attention in the . fifteen years but there is still a good deal of usion both about the *nature of the bone disorder* about the mechanism of the resulting neurological ects This confusion is reflected in the varied ication of such *terms as spondylosis osteo-* ritis disc protrusion, and degeneration of the e At first, workers were intent primarily on blishing the existence and character of the neuro cal syndromes due to abnormalities in the cervical e Following the lead given by Sir **RUSSELL** IN in his careful and thoughtful articles,[1 2] many rvers have added to the detailed descriptions of neurological patterns arising from involvement he cervical nerve roots.[3-5] Furthermore, both IN[1 2 4] and other workers including **SPILLANE** LLOYD,[6 7] have described the many different ifestations of changes in the spinal cord that may ound, and on p 171 of this issue Dr **CLARKE** rs attention to the frequency of this 'cervical lopathy'

he neurological effects of spondylosis are deter ed almost wholly by anatomical factors, and onal treatment must depend on correct apprecia of the anatomical derangements. The lack of nimity on the management of cervical radiculo- ny and myelopathy clearly reflects prevailing rtainty about pathogenesis The shadow of ilation of the lumbar intervertebral discs as a e of sciatica casts itself over all thought relating the cervical region, even though **FRYKHOLM**[5] ited to some very important differences between lumbar and cervical regions and remarked on the tive infrequency of soft nuclear herniations in the ical region Professor **CAVE**, Mr **GRIFFITHS** and **WHITELEY** in an article that also appears this k emphasise the importance of osteo-arthritis of neurocentral joints of Luschka in the production oot symptoms One very interesting feature of e of their cases was the absence of abnormality he disc space when osteo-arthritis of [illegible] ts was displayed radiographically *This finding* suggests that disc degeneration is not a sine-qua non of cervical osteo-arthritis, although the two often co-exist Not everyone will agree with the implication that radiculopathy is due rather to this osteo arthritis than to lateral herniation of the disc, but the observations and excellent illustrations give additional point to the view that many different factors may bring *about the neurological end results of cervical spondylosis* From published reports cervical spondylosis emerges as a pathological miscellany in which the *various subdivisions* may *be related both in nature* and in development The spinal abnormalities affect the cord and roots by pressure either on the nerve *tissues themselves* or on their nutrient blood vessels as **LIVERSEDGE** et al[8] suggested, and fibrosis of the root sleeve may play a part in the radicular symptoms[9] This pressure ischæmia may be aggravated by continued movements of the spine[10] It follows that therapy should be directed towards removing any or all of these factors, and will vary with the nature, duration, and extent of the skeletal lesion Here dogmatism still has no place, but it does now seem possible to lay down certain guiding principles for the management of the various types of disorder

It is quite clear that soft protrusions of the cervical discs may follow trauma and produce immediate symptoms ranging, according to their size and location from acute brachial neuritis to complete paraplegia or quadriplegia Such *symptoms* if severe enough require early operative relief for the removal of pressure In a sense this type of lesions is outside the bounds of cervical spondylosis But in some cases the initial symptoms subside with rest and perhaps by conservative remedies while in others the protrusions cause virtually no symptoms and in either event the stage is set for the later calcification of the protrusion, osteophyte formation, and the subsequent picture of the "single-disc" type of spondylosis noted in 18 of the 38 cases described by BRAIN et al[2] If these effects of trauma involve two or more levels—as they may—the ultimate picture may resemble radiographically and neurologically the full scale degenerative type of spondylosis *In this type of* case removal of the source of pressure on the cord might seem the ideal remedy but wrestling with an *ivory hard bar or knob in the vicinity of the highly* vulnerable cervical cord can be most unrewarding for surgeon and patient alike The presence of abnor*malities at more than one level*, particularly if demonstrated on [illegible] seems to contra-ind[illegible] direct approach to the [illegible] lesion but in [illegible] cases there is something to be said for la[illegible] even though the final results of such [illegible] still unknown Alternatively the [illegible] [illegible] weeks or months of a collar [illegible] [illegible] or plaster will alleviate or [illegible] symptoms but [illegible] like [illegible] [illegible] [illegible]

The factors other than disc protrusion that may influence the final picture of cervical spondylosis are becoming a little clearer PALLIS et al [11] investigated 50 hospital inpatients over the age of 50, and detected narrowing of the spinal canal in three-quarters of this total, and narrowing of the intervertebral foramina also in three-quarters, but such spondylotic change was not always associated with neurological abnormalities In some cases these affections may have originated in a disc herniation of one sort or another, but shrinkage of disc spaces, not necessarily accompanied by actual herniation, and osteo arthritic changes of the cervical spine seem to be included in the price to be paid for longevity There is, it seems, an osteochondrous degenerative process ranging from generalised osteo-arthritis (with spondylosis from top to bottom of the spine) to the more localised affection of the neurocentral joints now described by Professor CAVE and previously mentioned by PALLIS et al [11] The neurological consequences of this type of spinal disorder are similar to those of the chronic spondylosis related to disc protrusion, and sometimes both factors may operate in a single case It follows that the management of this type of case will be similar to that of the spondylosis resulting from disc protrusion, with a more definite tendency towards conservatism Professor CAVE suggests that neurocentral apophysectomy of the affected joints is the only means of permanent cure for the lesions he describes, but as he himself hints, the technical difficulties seem insuperable If more than one abnormality is revealed radiographically, unroofing of the theca by laminectomy is similarly of doubtful value It seems, then, that application of a collar is likely to be the only means of alleviating this condition, and here again radicular manifestations will be more amenable than those of myelopathy Manipulation and traction and even "reablement exercises" may aggravate any or all of the neurological symptoms in these cases, and in this connection we may recall Sir CHARLES SYMONDS's [12] account of the rôle of trauma, or even ordinary movements, in precipitating neurological disabilities in the patient with cervical spondylosis It has been suggested that the spine might be fused, either as a complete treatment or as an adjunct to laminectomy, but the benefits of such action have not yet been clearly established Meanwhile it behoves us as we grow older to adopt a more regal posture and bearing, and to avoid all rapid, undignified movements of the head and neck, if we are to escape the manifold dangers of radiculopathy and myelopathy

Our new awareness of the frequency of cervical spondylosis brings in its train an important clinical responsibility Many neurological diseases may be simulated by cervical myelopathy and radiculopathy due to spondylosis, but there is always a danger that such another disorder may be present in a patient whose cervical spine is radiographically abnormal If the intrinsic neurological disease were itself degenerative or untreatable, the confusion with spondylotic myelopathy would not be of great practical importance But if the second lesion were, for instance, a benign tumour of the spinal cord or subacute combined degeneration of the cord, the attribution of symptoms to the coincidental spondylosis could be tragic

## Group Discussion

[1] Group Discussion in Educational, Social and Working Life
lished by the Central Council for Health Education, T
House London W C 1 Pp 92 3s 6d

group leader someone who can guide the argument otrusively but firmly towards a definite decision re possible, the leader should have special know o of the topic under consideration thus a local ly doctor might preside at a discussion on The of the Elderly, or a local magistrate at a dis ion on Juvenile Delinquency It is important he should be able to put the members of the p at their ease and make each participant feel his contribution is valuable and interesting etimes, as one writer says, his function is merely merge the group and disappear —since the ussion may proceed even more energetically in absence But usually it is helpful if the leader s up at the end of the meeting, and formulates in le terms the proposed course of action.

the past twenty years the principle has been with singular success in psychotherapy, and oup psychotherapy is now a recognised way of ing some mental disorders At first sight there s to be little resemblance between a psycho apy group and a group of persons meeting to ider a difficult social question The latter attend heir own initiative, and have common interests aims The members of the psychotherapy group he other hand are selected arbitrarily by the hiatrist, often they meet as complete strangers they seldom have anything but their illness in mon Yet fundamentally the purpose of the groups is the same both overcome their diffi es by sharing them, and both gain strength from realisation that their troubles are not unique e psychotherapy group the patient " re-discovers ationally the home-spun truth, that in helping s, he best helps himself ' And that after all principle which applies to every section of society

## Recording Alimentary Movement

JR knowledge of stomach and bowel movements an is imprecise partly because no permanent l record can be made, unfortunately man has he transparency of the telescopic fish *Carassius us* Most investigations into the activities of the ntary tract have been biochemical and chemical in consequence our minds are trained and even ed, to the idea of chemical or hormonal causes of ic ulceration—the very term peptic denotes limitation Yet the constant location of duodenal in the first part of the duodenum suggests that echanical force with which chyme is ejected from ylorus may play a part it would be instructive o a ciné film in slow motion of a barium meal

e pioneer of X ray cinematography was MACIN [1] who in 1897 demonstrated the movements of g s leg on 40 ft of film He used both the direct indirect methods

the *direct method* a strip of X ray film is later graphed on to ciné-film By this method BARCLAY [2] found that initial filming at the maximum rate of mes per second [3] caused much vibration owing to eight of heavy moving parts and they had diffi in interrupting the electrical current at such short als since contactors for X ray apparatus are ally constructed for heavy currents and are therefore too cumbersome for rapid work The method was used for investigating circulation in animals and it should therefore suffice for the slower movements of the alimentary tract. With patients X ray dosage is a real problem, though the dosage can be curtailed by means of intensifying screens, which utilise the fluorescent effect of X rays on such substances as cadmium tungstate thus the proportion of film darkening due to X rays can be reduced to 2% the rest being the result of light rays stimulated by the X rays on the screen

Paradoxically the *indirect method* seems more direct The photograph is not taken direct on to X ray film; instead ordinary pictures are taken from a fluorescent screen REYNOLDS [4] made this method practicable by his device for turning off the X rays when the film was being moved and by using a ciné-lens of aperture f/085 But the X ray milliamperage must be high to obtain sufficient fluorescence, and if injury from irradiation *is to be avoided the exposures must be brief*; REYNOLDS limited exposure of any one area to 10 seconds

In man therefore these methods are cumbersome expensive and potentially dangerous But now with image amplifiers much greater brightness is achieved with smaller doses of X rays and so more protracted exposures are feasible These amplifiers convert the energy in which the image is cast from light on the fluorescent screen to electron emission from a photo electric surface These electrons do not radiate in all directions in the manner of light so almost the whole emission can be amplified and drawn by a positive pole through electrostatic fields which concentrate and focus them on to a small target screen where they are once more converted into light this is photographed on cine film and passed through a telescopic system for simultaneous direct vision Clearly the length of the amplifier tube is directly related to the size of the output screen the bigger the screen, the longer is the vacuum tube, and the more difficult is the apparatus to construct Accordingly screens have been limited to 5 inches square which is just too small for study of the alimentary canal in the adult but it cannot be long before these mechanical difficulties are solved The gain will be great for unit time of exposure the X ray milliamperage required is reduced two hundred times and according to COLTMAN [5] brightness can be amplified five hundred fold—which brings the image out of the region of rod vision into that of cone vision, where stereoscopy is possible

So much for direct visual recording of alimentary movements Much has been done in the past by way of indirect analysis of peristaltic and pressure waves The balloon and tambour system recording on a kymograph is attractive because of its simplicity its limitations have been overlooked A balloon is a shape unnatural to the alimentary tract the physiological response which it engenders and then records is unlikely to be related closely to normal waves of contraction From the physical aspect the system is most unsatisfactory, nobody would consider using a closed balloon tambour system for anything but registering contraction waves but even in a balloon/water manometer system the pressures recorded are not directly intraluminal since the size shape volume and elasticity of the balloon influence the pressures passing through the system [6] For recording contraction and pressure waves the intraluminal portion of the system must be small in bulk to avoid recording an alimentary response due to the apparatus, **ABBOTT** et al [7] devised a system of small metal capsules, each containing a flexible diaphragm carrying an electric contact which closed at known pressures The method was ingenious but complex, but it does indicate that strain gauges could perhaps be useful **BRODY** et al [6] measured pressure changes with an open tube in the gut and an optical manometer, the mass introduced was small, and the inertia within the system very slight

[6] Brody D A Werle J M, Meschan, I Quigley J P *Physiol* 1940 130 791

Motility has been investigated by the even less direct method of measuring electrical potentials **ALVAREZ** [8] applied electrodes to the thin abdominal wall of a small old woman and compared the gastrogram with visible peristalsis At that time he could use an intragastric electrode only in patients with achlorhydria, on account of the voltage variations set up, in others, by fluctuations in the level of acid in the gastric juice bathing the terminals Using non-polarisable electrodes, one in the stomach and one on the skin, **ADAIR** and **GOODMAN** [9] found a difference of potential (the stomach being negative to skin) which increased after milk was ingested Later in experimental work with **QUIGLEY** and **BARCROFT**,[10] these workers came to the conclusion that th potential did not depend on the pH of the contents or on activity due to secretion or m **ALVAREZ** and **MAHONEY** [11] had already d changes in potential at times when no [illegible] could be observed Now **MORTON** [12] has dev an electrogastrograph on which he records current due to secretory activity with sup alternating current due to action-potentials from motility He uses the same system of non-p sable monopolar electrodes with the active p the stomach, placing the independent el the skin over the right delto pectoral groove r shoulder, and he believes that the total of built up at cellular and tissue interfaces, which barriers to diffusion between the two terminals be nearly zero and can therefore be ignored. H hopes that these methods may make clear the nism of motility Both he and **GOODMAN** [13] him have diagnosed early carcinoma of the from the form of the tracing, and **MORTON** ha demonstrated variations from normal pattern presence of peptic ulcer, and has differentiated b gastric and duodenal ulcer These empirical f suggest that the electrogastrograph may prove in clinical practice, but the method is still experimental stage

## PALLIATION IN CANCER

DESPITE heartening progress in the treatment of malignant disease there are still many patients with cancer for whom there can be no cure The management of each one of these has its own peculiar difficulties, but it is clear from a discussion, on Jan 5, by the section of surgery of the Royal Society of Medicine that there is a wide choice of useful palliative techniques

The limitations of surgery in this field were clearly stated by Mr H T Simmons One of the surgeon's most valuable contributions is in the relief of pain by removal of the primary neoplasm, but the circumstances in which this should be attempted depend largely on his judgment and experience Incomplete excision of a tongue cancer can cause only harm, whereas in carcinoma of the stomach gastro enterostomy alone is most unsatisfactory In the small and large intestine the relief of obstruction by a by-pass is immensely valuable, but colostomy in an old man with an inoperable rectal cancer only adds another trouble and does nothing to relieve the distressing bleeding and tenesmus Mr H R Thompson has found, from the records of St Mark's Hospital, that 17% of a large number of patients submitted to what was believed to be a palliative operation were still alive 5 years later But often, said Mr Simmons, a heroic operation is planned and executed only to show the surgeon's audacity and technical skill Such an operation will be justified only if it brings considerable relief

Hitherto full advantage has perhaps not been taken of the neurosurgeon's power to allay pain There is a reassuring precision in spinothalamic tractotomy for painful lesions in the lower half of the body, and division of the glossopharyngeal nerve and of the posterior roots of the upper cervical nerves for intractable mouth tumours is less attractive only because it involves a [illegible] complicated cerebellar exposure But Prof N [illegible]t frankly admitted the shortcomings of leucotomy, which leaves the physical aspects of unaffected although the patient ceases to be by its ravages Respite is bought only at the flattening and shallowing of the whole personality No less important than the relief is the preservation of essential neural funct example, when vision is threatened by an int metastasis or the spinal cord by an osseous depo

Hormonal therapy is clearly valuable in the of cancer of the parasexual organs, but its effec in any particular patient is largely unpredictabl mounting experience of adrenalectomy has prov the benefit may be dramatic, although we must to balance the severity of the operation agai palliation achieved A preliminary report fr Murray Falconer suggested that hypophysect technically possible, and that in the hands of ex we can expect an acceptably low mortality Th of work, with its accompanying problems of replacement, should be confined to centres with facilities The suggestion by one speaker that the ment of every patient with inoperable cancer sh considered by a panel of experts, each of whom the limitations of his own technique as a palliati regarded by the meeting with some misgivi care of the patient might pass to a "muddle of d

Of drugs, morphine is our standby in the stages "it exists to be given and not merely to held" Nurses are often reluctant to give it in doses, even though the problem of addiction seldo There is too much persistence of the Calvinistic thought, which prompted Professor Dott to q Scots saying that "ye canna buy the grace o' dear" On the other hand, the patient will benefit if a diagnosis of inoperable cancer is made the justification for administering an its greatest merit is in the relief of pain and reserve it for this purpose There can be no har early and continuous use of analgesics, and speakers made a good case for administering chlo zine, especially when vomiting is intractable o burden of care of the patient in his latter days mainly on his general practitioner whose point of was expressed by Dr G F Abercrombie He lained that hospitals too often fail to tell their nts anything with the natural result that the general itioner is put at a grave disadvantage from the very t But it was clear from the later discussion that veryone would willingly follow his practice of always g cancer patients the truth He argued that we ly underestimate their ability "to take it" id been deeply impressed by their fortitude and ie mental adjustment that seemed to follow quite ully He saw nothing good in the dissimulation by r and relatives that must inevitably follow when rue diagnosis is withheld, and had never had good n to regret telling the truth In this regard we d campaign strenuously against the view so monly held by laymen that a cancer death is always ing and painful Dr P W Nathan took quite the ite point of view He felt that we have no moral to reveal the truth and that there is a good case for ultivated deliberate lie To judge by the views ssed by other speakers, the majority practice somewhere between the two extremes In the early the patient's powers of self deception are raged, and the truth is told only when the physician isfied that the patient wants it or when this seems in the interest of himself or of his relatives. By we may sometimes deny a responsible patient ly chance of putting his house in order Dr C J r wisely put the case for frequent visiting in such even when nothing overt is achieved often, there is a close bond of understanding between t and doctor there comes a time when the truth igh unspoken is equally revealed by an exchanged or a squeeze of the hand Mr Simmons deplored sual attitude of the surgeon who leaves the inoper ase to his registrar at the end of the list At no must the patient feel abandoned and the nurses and latives no less need constant encouragement

seems clear from this discussion that the choice thod will depend partly on the site of the tumour its natural history but even more on the patient's ter age and responsibilities and his position in

## STERILISATION OF SYRINGES

RY housewife knows that the hottest part of ing-oven is near the top Darmady and Brock,[1] y thorough experiments with ovens for sterilising es found a much higher temperature near the top linary electric ovens and this difference proved greater with two gas heated ovens An alternative d—namely boiling—was investigated by testing thermocouples the temperature attained by indi syringes; and it was found that if the syringe rapped in lint before being placed in boiling water was not reached for 5 minutes or longer The alternative—autoclaving—is unsatisfactory because ringes have first to be taken apart

rly if ovens are to be used for sterilising syringes hing must be done to equalise the temperature hout the whole space, otherwise the syringes near the top of the oven may be overheated while t the bottom may not be sterilised Darmady and therefore tested electric ovens in which the circula f hot air was aided by fans In such ovens the rature of the syringes provided that they were not d too tightly rose rapidly and evenly to the desired What this level should be seems still to be in e and the authors cite suggestions varying from for 1 hour (electric oven with fan) to 160°–180 C hours A report[2] issued by the Ministry of Health specifies 160° ± 5°C for not less than 1 hour Since spores of different organisms have different thermal death points Darmady and Brock suggest that an authoritative body should define the organism to be used for checking sterilisation by dry heat

From this valuable report certain principles emerge for those setting up a syringe service only electric ovens with fans are suitable the oven must not be overloaded with syringes, which must be packed loosely and the temperature of the syringe should be checked against the temperature recorded by the oven's thermometer Finally Darmady and Brock show that an electric oven with fan seems to work better if loaded while still hot—which is contrary to the M.R.C memorandum[3] and to the Ministry's report[2]

## THE HOME CARE TEAM

WE all know that far too many people knock on the door of the Englishman's castle and offer advice on health, infant welfare surgical appliances, housing drains school attendance delinquent behaviour tuberculosis mental ill health, and a variety of other topics and that no two of these specialists will necessarily give the same advice even when (as occasionally happens) they are talking about the same thing It has always seemed desirable to reduce their numbers and to have instead a few people with a broader outlook Some think that if the health visitor and the district nurse could have more scope and appropriate training they could with the family doctor take in most aspects of family life and that being already trusted family friends they are the right people to undertake this broad care

The opportunities for health teaching open to the district nurse working with the family doctor have lately been described by Dr J L Burn[4] medical officer of health for Salford Home care he thinks is bound to gain in importance psychological medical and financial reasons all favour the complementary use of the home and the hospital in the care of the sick Domiciliary visits by specialists—which he regards as one of the fine achievements of the National Health Service—have already enabled many people to stay out of hospital and have also ensured that many who need hospital treatment are admitted without undue delay This service in his opinion is being well and widely used in one region only in 1953 some 20 000 domiciliary visits were paid by consultants, and the numbers steadily increase Earlier discharge of patients from hospital is now being arranged in some areas though some hospitals—not confident of the standard of home care which now can (and should) be provided—hesitate to attempt it as a fixed policy If only one patient in twenty was discharged earlier, to the care of his family doctor and his district nurse it would greatly reduce the blockage of hospital beds and help the people on our hospital waiting lists

District nurses could be used more fully Dr Burn thinks in the care of sick children; these sometimes get less skilled nursing than they need—the nurse like the home help being expected to give her attention almost exclusively to old people Nor do pædiatricians get called in as freely as other specialists; and indeed the family doctor himself may not be called in till the last minute Such delays mean that some children's lives are lost unnecessarily Dr Burn urges that the health visitor should pay more routine visits to babies in "black-spot" areas and should press the parents to call in the doctor early when a baby is ill. She should also have far more official opportunity for collaborating with the district nurse who in turn should be in closer touch with the doctor All three—or their representatives—should have the opportunity of joining in discussions at the local health department when policy is being decided, and at Salford this is done

[3] Medical Research Council War Memorandum no 15 H.M. Stationery Office, 1945

[4] *Nursing Times* 1954 50 11

The district nurse has "the unique and privileged opportunity" of being able to observe the whole needs of the families she attends, and she should be able, in his view, to call in, when necessary, the aid of the health visitor, the home help, the sanitary inspector, or any other useful person available under the N H S Some are already doing this, but a few, he hints, cling a little too rigidly to their prescribed duties He mentions the good spirit he found in the William Budd Health Centre at Bristol, where the health team—doctors, home nurse, midwife, and health visitor—worked keenly together in specially built premises According to them, "the most important room in the building" was the staff room, where they met daily to discuss their patients and their patients' families

The nurse's work, Dr Burns thinks, could be lightened if we employed less highly skilled people for some of the routine tasks—to give blanket baths, for instance We might also improve our supplementary services—arranging for "sitters up," making the loan of equipment easier, and providing laundry services for incontinent patients Another way of saving time would be for the public-health department to run a central syringe service, supplying doctors and nurses with all the sterilised syringes they need, and possibly with all other sterilised equipment Again, a daily clinic might be sponsored by the public health department, where the district nurse could give injections to all the ambulant patients on her list who needed them He mentioned, too, the opportunities both nurse and doctor have for health education, "supporting each other and encouraging the patients and their families in the promotion of health and the prevention of disease"

## EPITHELIOMA CUNICULATUM

The recognition of a new pattern in disease is one of the satisfying features of experience in the practice of medicine Such a piece of knowledge has been put on record by Aird and his colleagues [1]

They found, in a man aged 64, a tumour of the sole of the foot comprising an irregular bulbous mass of a curiously "squashy" consistence, on pressure greasy, foul smelling, "tooth-paste" material was expressed from the mouths of a series of sinuses, each opening on the top of one of the bulges Although the tumour had penetrated through between the metatarsals to present on the dorsum there was no hint of destruction of bone or of tendons—an impression which was confirmed when a sagittal section showed it to be a well defined tumour expanding into the soft parts The histological picture was exceedingly confused The tumour was made up of a complex pattern of anastomosing tracks, each lined by squamous epithelium and full of degenerating keratin It was no surprise that a small biopsy fragment led to no clear understanding of the orientation of the various cell layers A precisely similar clinical and histological picture was later found in a second case, again in the forefoot of an elderly man, and a third matching specimen was collected from the shelves of a pathological museum

From a study of these three cases Aird et al conclude that the lesion is a well differentiated squamous carcinoma of low malignancy which is modified by pressure Walking, it is presumed, forces the tumour up into the soft parts, in a manner reminiscent of corns and of plantar warts, and here keratin accumulates in cystic spaces which later empty through sinuses, to leave a distinctive soft and bulky tumour mass Aird et al believe that this form of squamous carcinoma is peculiar to the foot, and for it they suggest the descriptive term "epithelioma cuniculatum," from the resemblance of the tracks to the burrows of a warren There was no evidence of distant metastases, and treatment each case by amputation

## PHYSIOTHERAPY EXAMINED

The tremendous medical advances of the pa years have included no outstanding innovatio field of physiotherapy In the late war a small e getic group of remedial gymnasts was formed Services, and the introduction of its methods into hospitals has marked a shift from passivity to a by the patient in treatment On the whole, b physiotherapy has latterly tended to be one of th conservative branches of medicine, and las Tegner [1] boldly called for reconsideration of the several forms of treatment whose worth has too often been taken for granted This enth borne fruit, for on Dec 8 the section of physical m of the Royal Society of Medicine met to discuss t and Abuse of Physiotherapy, and, in her remarks, Dr Doris Baker, president of the sectio that this was the natural answer to Tegner's ch

Dr A C Boyle pointed out that much of therapy is directed at painful conditions of the lo system, some of which are apt to clear up of th accord Physical methods, which are commonly sive, must not be prescribed as a mere placebo rest, and activity might each be beneficial, and c planned physical treatment had a place in certain pulmonary diseases, and neurological d —though even in these conditions much treatm was at present being applied was useless Sq Leader C B Wynn Parry went so far as to re gether microwave diathermy, ultrasonics, and m and he thought that the claims made for t constant current treatments, short wave di massage, and ultraviolet irradiation were exces that these remedies were grossly over prescribed emphasis of Dr A T Richardson's remarks w particular contribution that the specialist in p medicine can make to diagnosis and prognosis his knowledge of electrical changes Dr G O found that ultraviolet irradiation had a limite in dermatology he regarded the prescription of therapy in peripheral-vascular disease as quite unj Dr F S Cooksey welcomed the scientific inte that was now going on, and strongly advised the therapist to abandon out of date methods of tr and follow the medical profession in its scientific Finally, Dr W R Grant described physiother drug of addiction

It will be seen, therefore, that members of this section are by no means backward in scrutin forms of treatment which, during the years, ha allowed to claim what was probably too large a the practice of physical medicine

## THE INCIDENCE OF
## CANCER OF THE LARYNX
### LATION TO THE INCIDENCE OF CANCER OF THE BRONCHI

JAMES MAXWELL
M.D Lond. F R C P

will refuse to admit that there has been a great
e in the incidence of cancer of the lung or
ial carcinoma within the past thirty years and
blem of this disease has acquired an added urgency
e of the suggestion that this increase may be
related to the rise in consumption of cigarettes
the same period. It is not always remembered
er that this question of the action of inhaled
t substances upon the mucous membrane of
spiratory tract has been mooted for a long

ongst the first to suggest that the inhalation of
t substances was a possible cause of bronchial
was Duguid[1] who in 1927 reported a high
tion of cases in outdoor workers Two years later
ell and Nicholson[2] discussed the incidence of the
ion and considered the possibility that amongst
factors, tobacco-smoking could be an important
At that time it was not even certain that the
was increasing in frequency and they confined
lves to the suggestion that if cigarettes were an
ant cause it would be reasonable to expect a
rtionate increase in females affected by this type
er, in view of the great increase in the number of
smokers at that time

933 Maxwell and Hogg[3] reviewed the incidence
yngeal cancer as revealed by the Registrar
l s figures over the twenty years 1911–30 It was
that the concentration of any inhaled carcino
substance would be higher when it struck the
*than when it reached the individual bronchi* and
erefore sought to discover whether cancer of the
showed the same apparent increase as cancer of
g Reasons were given for accepting the accuracy
figures used for a *comparatively superficial form*
gnant disease and the figures for cancer of the
gus and of the tongue were included for com
The results showed a slight increase in the
tion of cases of cancer of the larynx to cancer in
from 1·29% in 1911 to 1·92% in 1930 Cancer
œsophagus was found to have maintained its
tion whereas there had been a slight fall in the
ce of cancer of the tongue No definite con
s could be drawn from the figures quoted but it
ggested that the figures for laryngeal cancer
a useful basis for comparison for it was then
in whether bronchial carcinoma *was increasing*
uency or was merely being diagnosed more

*now certain that bronchial cancer has increased*
still increasing in frequency and the question
led carcinogenic substances has become a matter
nt importance both to the consumer and to the
of tobacco I have accordingly extended the
s investigation by examining a comparable series
es for cancer of the larynx in this country during
t ten years The results are set out in the accom
table figures for carcinoma of the œsophagus
he tongue being again included

It will be noted that cancer in general continues to increase steadily every year (There is reason to expect such an increase and the factors concerned have often been discussed) For cancer of the larynx however there has been no absolute increase in the annual returns for the past thirty years and consequently the proportion of laryngeal cases to the cancer total has actually fallen and indeed appears to be lower than it was before the 1914 war Cancer of the œsophagus shows a similar decrease and cancer of the tongue is becoming noticeably less common as the years go by

The increase in bronchial cancer is now universally admitted Yet the figures quoted here make it equally clear that cancer of the larynx is diminishing rather than increasing If the inhalation of carcinogenic substances is really an important factor in the production of bronchial carcinoma what can be the reason for this diminution? The main contact with any inhaled irritant must be in the larynx and the concentration of any such substance must be much less in the more distal parts of the bronchial tree Therefore if tobacco smoke or indeed any other inhaled irritant is concerned in causing malignant change in the bronchial epithelium the relative freedom of the larynx from cancer can be explained only by assuming that its mucous membrane is much less sensitive to the inhaled agent than is the mucous membrane of the bronchi Yet our knowledge of the action of most carcinogenic substances indicates that they act quite strongly on squamous epithelium and it would have been reasonable to expect that during a period when cancer of the bronchi has increased so considerably there would have been at least a perceptible increase in cancer of the larynx As there has been no such increase we must I *think conclude that whether or not tobacco smoke is a* factor in the production of bronchial carcinoma some hidden and hitherto unsuspected factor is responsible for the astonishing increase in cancer of the lung

TABLE SHOWING THE INCIDENCE OF MALIGNANT DISEASE OF THE LARYNX, TONGUE AND ŒSOPHAGUS IN ENGLAND AND WALES 1913–52

(The figures for 1911 1921 and 1930 are included for comparison)

| Year | Total deaths from malignant disease | Total deaths from cancer of | | | Percentage of all cases of malignant disease | | |
|---|---|---|---|---|---|---|---|
| | | Larynx | Œsophagus | Tongue | Larynx | Œsophagus | Tongue |
| 1911 | 35 902 | 462 | 1451 | 978 | 1·29 | 4·05 | 2·[illegible] |
| 1921 | 46 093 | 779 | 1907 | 1[illegible]5 | 1·69 | 4·14 | [illegible] |
| 1930 | 57 883 | 1117 | 2[illegible]00 | 1[illegible]10 | 1·9[illegible] | 3·90 | 2·09 |
| 1913 | 73 684 | 1027 | 2377 | 900 | 1·39 | [illegible] | 1·2[illegible] |
| 1914 | 73 497 | 993 | [illegible]196 | 912 | 1·3[illegible] | [illegible] | 1·2[illegible] |
| 1915 | 75 712 | 993 | 2268 | 802 | 1·31 | [illegible] | 1·06 |
| 1916 | 77 616 | 1010 | 2[illegible]63 | 75 | 1·30 | [illegible] | [illegible] |
| 1917 | 79 781 | 972 | 2352 | 7[illegible]0 | 1·22 | [illegible] | 0·91 |
| 1918 | 81 655 | 103[illegible] | 2311 | 718 | 1·2[illegible] | 2·83 | 0·88 |
| 1919 | 83 [illegible]01 | 986 | 2226 | 865 | 1·10 | 2·6 | 0·79 |
| 1950 | 85 270 | 991 | [illegible]316 | 671 | 1·16 | [illegible]·75 | 0·78 |
| 1951 | 86 080 | 1007 | 2340 | 647 | 1·17 | [illegible] | 0·76 |
| 1952 | 87 612 | 911 | 23[illegible]5 | 586 | 1·08 | 2·6[illegible] | 0·67 |

#### CONCLUSION

It is now certain that cancer of the larynx has not increased in frequency during the very period in which cancer of the bronchi and lungs has become very much more common It is difficult to understand why this should be so if the inhalation of a carcinogenic substance is a vital factor in producing cancer in the respiratory tract

# Medical Education

## THE FIRST FOUR YEARS

### A Plea for a Different and More Vocational Curriculum for Medical Students *

R A Q O'MEARA
M A, M D, Sc D Dubl, F R C P I, D P H
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF DUBLIN

To produce beneficial results at student level, recommendations as to improvements in the methods of teaching must be very specific Generalities are of little value

The four years of which I am speaking here are the premedical year (which in Irish medical schools is still, almost invariably, taken in the medical school or university), the two subsequent years, devoted mainly to the study of anatomy, physiology, histology, and biochemistry, and the third medical year, in which the student devotes most of his time to acquiring some knowledge of pathology or basic clinical science in its various branches and to the study of materia medica, pharmacology, and therapeutics During this year, and also for a short time at the end of his second medical year, the student attends hospital and receives elementary clinical instruction, but it is not my purpose to discuss this part of his education, except in the most incidental way My object is rather to dissect the teaching which the student receives in preparation for his clinical years

The period is one of great importance, because it is during this time that the general education of the student should be completed in order to give him the stamp of an educated man, while at the same time he has to be provided with the necessary technical knowledge in the basic sciences appertaining to medicine Is it possible to give him the advantages of a broad general education, combined with a high standard of medical training, in the time permitted? I believe that it is, but to achieve this happy result many revolutionary changes require to be made in the methods of teaching

### THE NEWCOMER

In Britain, it is quite usual for the instruction required for the premedical examination, or its equivalent, to be given at school But it has been a great mistake to separate the premedical year from the rest of the medical course It is greatly to be regretted that the final years at school should be occupied exclusively in the study of chemistry, physics, and biology, with entrance to a medical school in view, when these years should in reality be spent in more general cultural instruction in languages, literature, mathematics, history, and geography, with chemistry, physics, and biology as possible alternatives to additional languages as subjects of cultural value in their own right

While at school, the student does not learn how to learn He receives instruction in classes from teachers who help him over the more difficult hurdles in the set course He comes to the university untrained in any particular plan of learning For the first time he is thrown upon his own resources and has to find his own level. There is no doubt that individuals vary enormously in the methods of acquiring knowledge which they find best suited to their particular mentality, training, and outlook After a time, many students probably work out a system for themselves which they find gives reasonable satisfaction, there are many others, however, who never acquire a learning, but proceed as best they can and b sheer hard labour, and very often unreasoning tion, learn enough to satisfy their examin successive stages of the medical course What here is an advisory system for students to them, preferably individually or alternatively i groups, how best they may go about learning the they have to assimilate during the coming yea method which each student finds best for his own ments should be well established by the en premedical year and should stand to him there the rest of his medical course and, indeed, of his career

At the beginning of the premedical course and subsequent course, the students should be told w have to learn and why they are learning it O many of them are completely at sea as to why th to study a given subject, how they have to stu to obtain the maximum return for their eff where it fits into the pattern of medical studie lead, ultimately, to medical practice A medical system is thus envisaged, whereby students instructed at an early stage how to go about the subjects they will be required to master relevance of the subjects of the curriculum to t of medicine

The student cannot be expected to grasp, the relevance to the theory and practice of the subjects in his premedical course and in courses in anatomy, physiology, biochemistry pathology He may well seem to be far from the of the patient, where he conceives his proper in emulation of the doctors he has known and the teachers whom he admires In many respects, great pity that his first visits to hospital are now deferred But if it were to be explained to him standing success as a clinician and the inner satis knowledge well applied are, in reality, depend the mastery of these earlier subjects—he would content with their study What we, who are with these earlier phases of his medical educatio to consider is the best method of imparting in so as to help the student to acquire the mastery

Commencing with the premedical year, durin the student receives instruction in chemistry, botany, and zoology, we can see an courses which are highly relevant to his futu medical student and as a doctor

### CHEMISTRY

It is difficult to understand why chemistry (t slightly less extent, physics) has been taken out medical course proper Historically, rational me founded on chemistry and anatomy With the em of chemistry from alchemy, advances first be made in our understanding of physiological As chemistry advanced, so also advanced our kn of cellular life, of fermentation, of pharmacol therapeutics, until today it is possible with the chemist to conquer infections, to relieve pain prolong life, not merely in belief but in dem fact

The teaching of chemistry has passed out control of doctors, who formerly did much of it to the growth of the science and its incre plexity, this change is perhaps inevitable M many aspects of chemistry which are of great im in modern medicine are to be found in the more parts of the subject which, normally, only honours students would be required to know circumstances, it may appear difficult to pro

---

* Extracts from a presidential address given to the Dublin University Biological Association on Oct 30, 1954 The address appears in full in the January issue of the *Irish Journal of Medical Sciences*, and these extracts are d by courtesy of the Editor of that journal

n medical student with a course in chemistry at relevant and adequate and at the same time, ently simple. My experience in examining medical its in chemistry however, shows that they can e a highly competent theoretical knowledge of the t in a course which is not too long What is ed consequently is a clearly defined course on a standard textbook should be written

textbook would be like no existing textbook in stry and would be subject to frequent revision It give in simple terms the more important points in cal theory followed by a special treatment of nic chemistry based upon the periodic table e it would proceed to organic chemistry dealing in with the straight-chain and ring compounds and derivatives, from the point of view of structure ting the student with a consecutive and logical tion of the subject In both inorganic and organic stry selection of material for special mention would do in relation to its importance in medicine To xtent this has been done in the past, but there is time-lag between the recognition of the importance ne *aspects of chemistry in medicine and their* on in the premedical chemistry course. A similar ng tends to retain in the course as important to the nt many subjects which have long ceased to matter e instances from inorganic chemistry arsenic, and ormerly much stressed are now of little consequence other hand it is not many years since beryllium ntalum were mentioned in small print in quite large on inorganic chemistry but today each is of ance in medicine the first, because of its violently ve effects on the tissues; the second, because it nert The textbook would be further embellished ction on elementary physical chemistry in relation dicine, and would contain chapters written in opular style dealing with a variety of selected illustrating the importance of chemistry in ne.

h such a textbook the need for more than a few lectures would disappear and their place could be with advantage by tutorials and lecture demon ns to small groups Medical students should learn ro but they should be required to learn only a uations, those necessary for practical titrations urse of reactions could quite well be indicated by m showing the nature of the chemical change in n It is unnecessary to produce a balanced equa r the understanding of most reactions and in nstances, it is merely foolish since the equation ot *in fact* represent *the true course of the reaction*

student s studies in theoretical chemistry would pplemented by a practical course in which the sis would be upon those chemical procedures which kely to find of greatest use in his subsequent studies icine and in medical practice Thus he would do little qualitative analysis and that carefully d, but he would do many titrations so as to become ghly adept in the use of pipettes and other instru of chemical measurement In designing practicals r they be in chemistry or in other subjects one ear in mind their four fold purpose They serve n observation to train manual dexterity to aid derstanding of the theory of the subject and to t in the planning of experiments From the t s point of view the first three are the most ant

## PHYSICS

ing to physics the pattern observed for chemistry repeated There are many aspects of physics in general is a difficult subject on which special on could be focused from the medical point of view In any event one finds in teaching and examining students that those parts of physics which are relevant to their medical course and to medical experience are often forgotten

It is surprising how many students in their third medical year still do not understand the microscope and the way to use it to best advantage To cite another example when examining in hygiene one finds that few students understand the arrangements of the ordinary domestic hot water supply Involving as it does a knowledge of the elementary principles of hydrostatics, of conduction and convection of heat the hot-water supply of a house provides a simple practical example of the application of physical theory which is important to health It is in any event something which the doctor should know—if only as a family man, which most medical students are destined to become One may contrast the lack of knowledge of these simple but important questions with the advice once given to me by a predecessor of mine as examiner in physics to the effect that if information was slow in coming in the viva voce the question to ask was the laws of the transverse vibrations of strings This never *failed to elicit* a correct reply and the examiner and candidate parted on good terms The question was clearly a grinder s tip based on an imperfect notion of the importance of these laws to the functioning of the vocal cords

So in physics, as in chemistry what we require is a clearly defined course around which a textbook suited particularly to the needs of the medical student should be written The matter could be presented in such a way *that it did not lay too much emphasis upon the mathematical* approach to the subject which is that of the true physicist but is beyond the powers of the average medical student The elementary theory of physics and its practical applications in medicine could thus be made available in a relevant fashion supplemented by lectures and lecture demonstrations. As for practicals while some devoted to experiments proving the truths of physics may be desirable, however inadequately they maybe conducted by medical students it seems to me that much of the time devoted to practicals could be spent in becoming familiar with the working of instruments based on applications of physical theory, which are used in medicine and surgery To take a few examples when learning the theory of the screw should practical work not be directed to learning at the same time the uses of different types of screw how to thread a screw and so forth? And in optics once the properties of different kinds of mirrors lenses, and prisms had been *explained, the student might study the microscope*—taking a simple microscope to pieces and reassembling it Would it be absurd to suggest that he should start to use the ophthalmoscope the laryngoscope and similar instruments if not on the living subject, at least on models?

## BIOLOGY

Botany and zoology are subjects which linger in attachment to the medical course Each has its relevance but nowadays *it is mainly* to a *later phase* in the student s career than the premedical What is particularly needed at the early stage is a course in biology to explain to the student the nature of life starting with the smaller simple cells their elementary metabolism and mode of reproduction and from that proceeding to the more complex multicellular forms of life especially in the animal kingdom. This course should include an account of the differentiation of tissues and organs as one ascends the scale of life and of their functions An elementary introduction to the study of heredity and genetics should be included It is at a much later stage when the student is doing pathology that a short course [illegible] protozoology helminthology and possibly should be provided, together with some account of the pathogenic fungi

ESSENTIALS—AND EXTRAS

In the suggested approach to the preliminary medical subjects there is no intention of decrying the invaluable services to medicine which so many teachers in these subjects have rendered in the past and will continue in the future It would not be possible for them, in existing circumstances, to design courses along the suggested lines, since medical students have to be fitted into the general pattern of science instruction in the universities The proposed ad-hoc courses in chemistry, physics, and biology would require special staff and facilities My object is rather to suggest the adoption of the general principle that instruction of medical students in the subjects of the medical curriculum, during the first four years, should be regarded as technical instruction and that the content of the various courses should be adjusted accordingly As far as possible, this adjustment would lead to the adoption of set courses, in theory and practical work, considered adequate for the requirements of the average medical student, and on these courses the professional examinations would be conducted The operation of this plan would substantially shorten the time spent on professional studies and would enable the university to devote more time to the student's general education

The study of subjects of cultural value would occupy part of that time The subjects chosen would necessarily depend upon inclination and ability For some, perhaps, mathematics, for others classical or modern languages would be an attraction It is particularly desirable nowadays that doctors should learn languages First, there is the cultural value Whether the additional language studied be Irish, French, German, or one of the other European languages, the training is a cultural asset In addition, a language is an instrument of contact with our fellow men in other lands It is less easy for us, than for those who live on the Continent, to acquire a speaking knowledge of a language other than that which we normally use, but it becomes more worthwhile every day At medical conferences abroad, Irish and English delegates are noticeably far behind those of other countries in this respect

Again, the subjects of the medical curriculum in their wider scope are of cultural value With the teaching of these subjects for professional purposes restricted to essentials, there would still be wide fields for the more brilliant and enterprising students to explore Facilities should therefore be available for the pursuit of higher knowledge in any of these subjects by students who possess the necessary ability and inclination As a stimulus, particularly to such students, it is to be assumed that a programme of research will be in operation in all teaching departments

ANATOMY, PHYSIOLOGY, AND BIOCHEMISTRY

If we have delayed too long on the premedical course, it is because the subjects of this first year are well suited to illustrate the pattern of medical instruction as technical instruction During most of the next two years the student has to learn human anatomy, physiology, biochemistry, and histology One may claim at the outset that a sound relevant knowledge of physics and chemistry, gained during the courses suggested for the premedical year, would be a very great help in the study of physiology and biochemistry The courses would have been designed to prepare the student for the application of the laws, theory, and experimental methods of physics and [illegible]mistry to the living animal

[illegible] ay, however, is in a different category There is [illegible] tute in clinical medicine and surgery for an accurate knowledge of anatomy And such on which finesse in clinical diagnosis and sound in treatment so often depend, can only be obt the most diligent application Nowadays a real has arisen in the teaching of anatomy in man centres, owing to the shortage of subjects for d Without freely available facilities for dissection, to be expected that the student can achieve the of knowledge needed to enable him to place his will over the site of any structure in the body of or child and to indicate the approach to it Y the standard of anatomical knowledge which and surgical practice demands One is tempted t that the members of our profession should o as in the days before the passing of the Anat sign a pledge donating their remains after deat anatomists to be used for the proper instr students

Formal lectures to large classes in descrip systematic anatomy are of little value as comp lecture demonstrations to small groups Whe anatomy, however, one felt the need for a tory lectures to indicate the general design of and the nature and properties of its main system it would have been a help to know that the ske stitutes the framework to which the muscles a what muscles are and what they do, and th arrangements of the heart and blood vessels a nervous system Looking back on the early dissection, when one began what might b amateur exploratory anatomy in the region of t it would have made things easier to have know starting, the sort of things one had to look for, w came from and where they went

But no amount of knowledge of the position tures in the body is adequate without a their function , and the modern approach to the of physiology and biochemistry to medical directed primarily towards an understanding functions and requirements of the human, a from the animal, body has been a great a medical education It is bearing fruit, more a in the application of these sciences and their to clinical medicine One might be permitted the likewise that in the study of histology greater on the microscopic structure of human tissues would be an advantage A closer cooperation b pathologist and histologist might help to bring pathologists have access to relatively normal tissues and organs, as well as to those which a by disease The specimens at their disposal it is true, satisfy the more exacting requiremen normal histologist as to fixation and details o structure, but they are often sufficient for the of students in normal histology

CORRELATION AND INTEGRATION

The student requires to be told at interval subjects which he learns in some parts of t correlate with those of other parts In sugg many formal lectures should disappear, t being taken by lecture demonstrations and would also suggest that room should be made of correlation, for which there is a decided need lectures the student would have outlined to him he has learnt and is learning, and how the the programme and link up with other par course

At the end of the second medical year and third medical year, he attends hospital and be pathology or basic clinical science At the sa studies materia medica and therapeutics Unfo however, integration is lacking between diff pathology course on the one hand and between ction in pathology and clinical instruction on the The lack of integration between pathology and edical aspects of bacteriology and immunology is table, but the lack of integration with clinical ine and surgery is even more serious The difficulty in part because the medical student nowadays hospital attendance so late in the medical course ather meaningless for the student when he hears tails of pathological changes found in cases which s never seen. The demonstration of lesions in ens only partly fills the void, and many students reat difficulty in understanding clinical disease they have not seen in terms of lesions demon d to them in specimens

medical sciences have changed more in character athology during the past twenty or thirty years ly has there been a great increase in knowledge much which was formerly vague theory is now hed on a basis of solid fact but during this period pathological lesions formerly common have now ly or totally disappeared. Two things about gy are outstanding One, that it is a great of correlation. Dealing as it does with the causes se, as well as all aspects of the changes which ught in the structure and functions of the body se it occupies a central position linking the earlier s of the medical course to itself and to clinical e and surgery The other is that today it occupies ition of arbiter of diagnosis Modern diagnosis e made in terms of the underlying pathological diagnosis by signs and symptoms alone is not t Pathology is necessarily a subject of enorm ide scope and is inseparable from clinical medicine, ecially during the third medical year it lends being taught as a technical subject in relation to medicine and surgery Its teaching can be so ed that within the framework of general pathology y relevant body of knowledge may be acquired student

o the end of this year, the general education of lent should be completed so that he is now as tructed in his chosen field of arts or science as other students of the university For the remain his medical course his instruction is mainly a or his clinical teachers but in the plan which I tlined he will have been specially prepared by a elevant technical training and a good general n to assimilate the knowledge and skill which ready to impart

### OBJECTS OF EDUCATION

uggestion is often made that one of the chief in the medical student s education should be to to think for himself. I would venture to suggest dment—*that the aim must rather be to teach* hink correctly. For right thinking there are two , knowledge and a trained mind Both are ome of sound education which not only provides ge and teaches the way to add to knowledge acquired, but also trains the mind to weigh and nowledge to the best advantage Education oo highly specialised is incomplete and imperfect. n dangerous The doctor whose knowledge is to the science of his profession is an imperfect o matter how well informed he may appear to dical matters In order to be fully worthy of ition in the activities of his profession, the ust be not merely a scientist but also a man of and of wide and varied understanding To ributes he will in time, add experience and and thus come nearer to perfection in his

## In England Now

*A Running Commentary by Peripatetic Correspondents*

We realise we are under the dew-claws of our cats, but at times I think they go too far When we lived on the second floor they arranged to come in and out by way of a tree, which meant we had to keep the sitting-room window open to the elements night and day It was a hardy life, but we won through When we moved to the third floor they looked out disapprovingly, and intimated that there was no tree At enormous expense we had a cat-ladder built by a distinguished firm of ladder makers It was one plank wide with balconies at intervals and could have presented no difficulty whatever to any able-bodied cat Snug when deposited in one of the balconies, looked pleased and expectant; Flute on the other hand, gave his well know impression of Macbeth at the sight of Banquo s ghost Then they both required us to take them in again The ladder-builders were beyond praise they made it two planks wide with a handrail and enlarged the balconies Snug immediately toddled sedately down and Flute, after a bad attack of the vapours rushed down and up again but of course as soon as that system was working smoothly we moved again, this time to a house in the country

The kitchen window presented no difficulties to the cats, but having it constantl open covered us with chilblains and meant we never got a hot meal so we called in George to make us a cat door It was a new idea to George, but he took to it with enthusiasm. We came home at nightfall to find he had bored a porthole in the backdoor about 5 in in diameter and 8 in from the ground—nicely placed for a burglar who had only to slip his hand in and draw back the bolt Mrs S who does for us was very pleased with it I spent the whole afternoon, she said training me cats and at the end they was coming in and out lovely Whatever they did for Mrs S they were determined to make us suffer They looked from us to the porthole, put two paws and a nose through and stared into the night, and when gently chivvied from the rear lumbered through in an uncouth bone-rapping manner that put our hearts through the wringer We telephoned to George who awed by our remorse promised to come next day and enlarge it. ' And while you re about it, we said hang a bit of wood across the hole so that they can push it open from either side that ll keep out the draught.

Home we came at eventide to find he had been as good as his word. He had hung a stout billet of timber in the opening which, so the cats intimated was quite beyond their strength to move. He had also transferred the bolt to a position out of reach of burglars where it interfered with the latch of the door Working fast we anchored the billet of timber out of the way by means of two screw eyes and a bit of string thus leaving the cat-door in the permanently open position A strong blast straight off Greenland whistled through the hole and filled the house. The cats repeated their act of peering timidly out and finally making the supreme sacrifice of struggling through bumping their rumps on the billet as they went and leaving lumps of fur on the woodwork We went despondently to bed An hour later we awakened to a noise of galloping Investigation revealed two cats charging up and down the hall and taking the cat-door like race-horses tails streaming heels tucked up behind Beaming indulgently we tiptoed back to bed

• • •

I have always found ambivalent a difficult word to slip easily into a conversation but I think it could be applied to the feelings of Edinburgh graduates who read in the *Times* of Jan 15 that the senate of their university had refused to allow the students to use the McEwan Hall for the installation of their new rector Most of us are sorry to hear that another tradition has lapsed but the installation of the rector is one of the more robust academic occasions, and anyone who recalls the indignant squawks of a clutch of outraged hens let loose in a flurry of toilet-rolls from the upper galleries of the McEwan Hall will not be able to withhold a certain measure pathy from the senate especially as £15,000 been spent on the redecoration of the hall thoughts I should perhaps reserve ambivalent to describe the feelings of Sir Sydney Smith, the new rector, who as chairman of the senate meeting must surely have announced this inhospitable decision with regret—and relief

* * *

DISTINGUISHED FOREIGN COLLEAGUE May I bother you about a small point which has puzzled me lately? As you know, I follow English medical publications closely, yet I do not seem to have heard of any of the authors of a series of authoritative papers which is appearing in *The Lancet* Sir Daniel Whiddon, for instance, where is he a professor of surgery? And Dr Harry Hawke—which great laboratory does he direct?

ME (heartily) I don't wonder you were puzzled But the explanation is quite simple These people are not writing under their own names They have chosen pseudonyms

D F C What a pious custom. No doubt in this way they commemorate revered physicians from your glorious past Sir Daniel Whiddon and Dr Harry Hawke belong, with Harvey, Osler and Lister, to the history of British Medicine

ME Well, you might think so, but actually, though it may seem rather odd, they aren't doctors at all You see, they all used to live near Widdicombe

D.F C Ah, then they all perhaps held chairs at the University of Widdicombe—no doubt a famous medieval seat of learning

ME Well, not exactly In a way they did all have seats at Widdicombe, but it wasn't so much chairs as seats on a horse They all took part in a famous ride

D.F C Ah, I understand They were the heroes of some dashing heroic exploit Perhaps they brought the good news from Widdicombe to Bristol I can see that gallant cavalcade of horsemen

ME Well, actually it wasn't quite like that either You see, though there were eight men, they all rode on the same horse

D F C Eight men on one horse! But I thought the English were always kind to animals Who owned the horse?

ME They borrowed the horse—a grey mare, rather a large one, I fancy It's all described in an old song The first verse goes something like this

Herr Tom Pearce, Herr Tom Pearce
Leih mir Deine graue Stute,
Dann reit' ich entlang am Ufer des Lea
Und besuche den Jahrmarkt in Widdicombe
Mit Herrn Brewer, Herrn Stewer, Herrn Gurney
Herrn Davey, und Onkel Thomas, et al

There, that explains the whole set-up

D F C Y—e—s Perhaps there are other verses?

ME Well there are, but I don't think you'd find them very helpful

D F C At least tell me what they did at Widdicombe

ME Oh, but I don't think they ever got there

D.F.C But what hindered them?

ME (uneasily) Well for one thing, the Mare stopped to make her will

D.F C To make her will!

ME That's right, old chap You know I was afraid you would find this part rather confusing

D F C I suppose the Mare will be writing to *The Lancet* herself next

ME Well you know, I shouldn't be at all surprised if she did

D F C Perhaps a contribution on veterinary medicine

ME Well, actually, I think she's more likely to write and tell the others where they get off

D.F C (infected at last) With all eight on her back at once she has every justification!

* * *

'SURGICAL POLYPHARMACY'[1]

Disease and cure
Are oft obscure
Physicians in such
Cases prescribe too much,
And that heresy
Is called "polypharmacy"

Surgeons remove
When in doubt,
Sundry bits and prove
Man can do without
The knife, thus erratic,
Is "polypragmatic"!

# Letters to the Editor

## ARGENTAFFINOMA AS ENDOCRINE

SIR,—You have twice[1] drawn attention to the endocrine function of argentaffinoma, in that carcinoid is associated with a syndrome manifested by flushing, right heart disease, distress, and diarrhœa. These manifesta attributable to release of serotonin (5 hydr mine) into the blood from the tumour This been supported by the preliminary demon hyperserotoninæmia in 2 patients exhibiting drome[2] You have also suggested that urinary 5 indole acetic acid (5H I A A)—the product of deamination of serotonin—might be increased in with malignant carcinoid and that a method assay might serve as a diagnostic test

We wish to report results of preliminary 3 cases of malignant carcinoid in which a recently developed method for assay of urine[3] In all 3 patients the daily excretion of was tremendously increased over normal contro

*Infusion of serotonin in control patients*—On received 31 mg of serotonin base over 60 minut other 10 4 mg over 30 minutes Both had local vein, and abdominal and bladder cramp when began or when the rates were increased. The hyperpnœa, and tingling and burning of the face during infusion There were moderate (11 and increases of mean arterial pressure Objectiv was flushed A wide experience with other pat serotonin by instantaneous intravenous injection that amounts of the order of 1 mg base are as m will tolerate because of the discomfort Urines we during and after infusion, and increments in 5H.I.A. were calculated by comparison with outputs other times The increment in the first patient over 3 hours and in the second 2 6 mg over outputs in other specimens were about 5 mg per Thus, the patients excreted as 5H I A.A. respec and 25% of the serotonin infused

*Malignant carcinoid*—Observations were ma patients One, a patient of Dr George Crile, jun., of Clinic, was an elderly man with widespread abd hepatic metastatic carcinoid, who did not exhibit the noid syndrome" Outputs of 5H I A A in his urine occasions were 65 and 230 µg per mg creatinine, or as many mg daily A biopsy of the tumour tissue for a rough bio assay in an anæsthetised dog, which a serotonin content of 0 9 mg per g of fresh tissue second, a woman who was flushing and had other istics of the syndrome, is under study by Colonel Mattingly, of the Walter Reed Hospital, Army Center, her urinary 5H.I A A was found to avera 350 mg per 24 hours Blood concentrations of were measured and found markedly increased ov The third case of malignant carcinoid, a patient of Dr Sampson, of San Francisco, yielded 142 mg of 5H 24 hours Clinical details of this patient are not at this time

These observations substantiate the sugge increased urinary 5H I A A is of diagnostic malignant carcinoid, The levels found in patients vastly exceed the 5–10 mg per 24 h in normal subjects,[4] or in a wide variety of dis

The infusion data indicate that less than circulating serotonin is excreted as 5H I A A, from seems that serotonin release in malignant carc range from 200 to 1000 mg per day or 0 1 to 0 minute

Attribution of the clinical syndrome to releas tonin alone is still questionable, since infusio

2 Pernow, B, Waldenström, J *Ibid*, p 951
3 Udenfriend S, Weissbach H Titus E O To be
4 Titus, E O, Udenfriend S *Fed Proc* 1954, 13, 411

t rates of about 0 5 mg per minute did not repro ushing or other aspects of the syndrome Further, ic flushing was not detected in one patient (that Crile) during several days observation in the of which great urinary outputs of 5H I A A were ed. The estimates of serum serotonin by Pernow aldenström [2] indicate the instantaneous presence od of some 30 mg of circulating serotonin This te seems excessive It is much more than control subjects tolerate by instantaneous injection ly by analogy with phæochromocytoma the istencies can be resolved by demonstration of ice of the patients to very large amounts of the and by supposing episodic release thereof It assumed that current studies to which the material communication is preliminary, will unravel this nism. At least the data show that measurement iary 5H.I A A is of diagnostic value in malignant oid, even when as in one of these three patients nical syndrome is not apparent

## PULMONARY EMBOLISM

—May I support Dr Aidin (Jan 8) in his plea for ent approach to the problem of thrombo-embolism? time ago [3] I put forward a hypothesis which was nconsistent with the work to which Dr Aidin and it is gratifying to find that doubt is again cast on the guilt of "venous stasis."

tories, the blood moves quickly in veins it moves less and in capillaries and sinusoids it moves very indeed. At the periphery of all vessels it is virtually ary and there is reason to believe that the blood in with the lining of the aorta is as still as the water anks of the Thames. It so happens that intravascular is most common in the arteries, and least common capillaries and sinusoids, but it does not follow that osis is the result of "arterial hurry"

esearch can be diverted into more profitable ls two advantages may accrue

The real cause of thrombo-embolism may be found ional treatment become possible

urgeons may refrain from chivvying their elderly s out of bed for a few minutes on the day after a operation I have often wondered what this astonishing supposed to achieve; the only tangible results I member are two apoplectic seizures and one acute failure

elieve that thrombo embolism may be related ding of the veins by products of the tissue kata which follows confinement to bed wasting disease, erative or other trauma This katabolic process a maximum about ten days after an "injury" ere is little evidence to suggest that the process modified by short term alterations in the diet— there is some evidence to the contrary

## RSENESS AND CORONARY THROMBOSIS

—The hoarseness noted by Dr Sarkany and dwood [4] as a sign of coronary thrombosis has been r to me for several years I do not think that it gn of coronary occlusion only; I have observed patients with no certain evidence of infarction I followed up for several years—though of course in these cases coronary thrombosis cannot be ruled out Laryngological examination never revealed any organic lesion I attribute the hoarseness to the exhaustion caused by severe and distressing pain

Berlin

R SCHEUER KARPIN

## THE BURNT CHILD

SIR —It is a pity that Dr Shannon in his excellent account last week of some of the aspects of the management of burnt children should sow jangling discord with his disparaging comment on physicians It is a pity that after looking at a burnt child he did not look further afield He might then have become aware of something of the contributions of physicians to the care of burnt children and learnt that there are physicians who have the training experience and outlook to help in these problems When the medical profession is being split into so many different specialties anyone who, by his written or spoken word creates factions and feuds is doing a disservice to medicine

Dr Shannon is of course right when he says that The custom of referring seriously ill patients to physicians for preoperative assessment is to be deplored There should be no question of reference the physician should be concerned with the child from the very first. Burnt children as other children are the better cared for when one or more of the team are familiar with the peculiar problems of childhood and are interested in their families and homes as well as their illness and Dr Shannon can be assured that the team that includes integrally a pædiatrician is more complete than that without

GEORGE DAVISON

## ADRENALECTOMY FOR HYPERTENSION

SIR,—Your excellent leading article of Jan 8 stimulates me to draw attention once more to the value of total bilateral adrenalectomy in cases of malignant hypertension.

I am aware that your editorial was not primarily concerned with cases which had progressed to the malignant phase but it is in these patients that the procedure can show such dramatic results. As you have stated, partial adrenalectomy and very occasionally total bilateral adrenalectomy have so often been combined with sympathectomy or hypotensive-drug therapy that it is difficult to assess the indications for adrenal surgery alone as opposed to other procedures You also point out that the blood pressure per se may not be influenced by adrenalectomy and for this reason I have hesitated to operate on any case with straightforward "essential hypertension. But most clinicians would agree that once papillœdema has developed the expectation of life can be measured in months not years so the patient has nothing to lose by undergoing total bilateral adrenalectomy

My experience of this operation is limited to twelve patients but the results have been most encouraging so far The five patients originally reported [1] continue to lead active useful lives, and five subsequent cases are equally encouraging The longest survivor (20 months) was probably the most acutely ill patient of the series having very severe cardiac failure with pulmonary congestion and pronounced visual disturbance

Cardiac failure with generalised œdema pulmonary congestion and severe eye changes are no contraindication to adrenalectomy, and can be dramatically relieved by the operation even if there is no change in the hypertension If the renal function is depressed the patient will die but it is difficult to define the limits of safety Both of my postoperative deaths were of pa with a urea clearance under 60% of normal

There is therefore no doubt that bila adrenalectomy can prolong life and re in cases of malignant hypertension pro are not seriously damaged If furt

Sarkany I Birdwood G F B *Ibid* 1954 ii [illegible]

1 Hanley H G *Proc R. Soc*

made, operation must be undertaken before the renal changes are too advanced In my experience so far, renal failure, as shown by our present crude tests, can develop suddenly and progress rapidly (in one case so rapidly that within three months the opportunity for surgery had passed), and probably renal function tests should be repeated more often in hypertensive patients, in the hope of detecting an early malignant phase This is certainly more important than repeated blood-pressure estimations, since hypertension per se appears to be simply a symptom of some disease that we have yet to discover

London W 1 HOWARD G HANLEY

## NOBECUTANE AS A WOUND DRESSING

SIR,—Since the introduction of 'Nobecutane' into this country, only one report on its use has appeared, when Rob and Eastcott[1] confirmed its value following application to 200 clean surgical wounds in patients resident in hospital During recent months, over 400 dressings on both inpatients and outpatients have been carried out at the Royal Free Hospital, and it was thought that our own experiences would be worth recording

Nobecutane is an acrylic resin dissolved in a mixture of acetic esters[2] It is inflammable until dry and has no effective bactericidal power In view of results previously reported and our own, the latter does not seem to be a disadvantage

*Method of Application*—As supplied at the present time, much of the fluid may be wasted, but experiments with a spray show this to be the ideal method of application. If a spray is not available, the standard bottle cap can be modified by inserting a narrow bore tube through a hole drilled in the screw cap, and an ordinary catheter spigot used to keep it closed when not in use This modification can easily be carried out in any hospital workshop The narrow bore tube allows the fluid to be used more sparingly, and a small brush will ensure that a thin layer is applied The brush can be cleaned with acetone, which will also remove the dressing if it cannot be stripped off cleanly with ordinary dressing forceps

*Infection*—In the occasional case, slight hyperæmia of the wound edges appears on the second or third postoperative day This subsides without local or systemic effects in the course of the following 24 to 48 hours In no "clean" surgical case has wound infection developed When used on potentially infected wounds in which an abscess has subsequently developed, the elasticity of the dressing has allowed the tissues to stretch, and its transparency enables progress to be observed The film is so resilient that it must be stripped off before adequate drainage can be obtained Where post operative drainage has been required through the original incision rather than through a separate "stab," the wound has in addition been covered in the immediate vicinity of the drainage tube by a gauze and wool dressing

*Intestinal Fistulæ*—In a limited number of cases we have used the method for protecting the skin round gastric, intestinal, and pancreatic fistulæ In one really uncontrolled colostomy it was not satisfactory because the fluid contents could not be limited to a reasonable surrounding area The dressing was stripped up from the periphery and could not be made to adhere again. In all other cases skin protection was adequate

*Cosmetic Results*—Since nobecutane has vasodilator properties, accurate hæmostasis is essential, but this is an advantage to the patient, if somewhat time consuming for the surgeon A continuous skin suture is more effective in controlling oozing than a series of interrupted sutures Providing this is inserted carefully, there is little risk of necrosis of the wound edges The continuous suture is also more easily removed In many cases we have not used skin sutures obtaining accurate co aptation of the skin edges by means of interrupted subcutaneous or intradermal sutures of fine plain catgut or silk This technique is especially valuable for thyroidectomy incisions and for other operations on exposed parts of the body A thin film of nobecutane helps to maintain this apposition and yet allows unrestricted movement

*Minor Outpatient Operations*—Although thes
are of little danger to life they do throw a cons
on a busy casualty department, where dressings
being removed and replaced In these cases
also proved satisfactory, despite the extra stra
the dressing during the patient's normal work. T
pain experienced during application to an
surface is no worse than that produced by dabbi
a cut

*Advantages and Disadvantages*—These have been
by Rob and Eastcott, and our experience
findings In addition we have found that immers
for ordinary washing purposes is not precluded, a
eases the work of the nursing staff One of our
even went swimming and returned the following d
dressing intact It has been said that patients
having their wounds exposed to view This has n
experience, for the vast majority of patients
able to move about in comfort—and to compare
their fellows and to show them to their visitors.

Nobecutane is a satisfactory surgical dressi
inpatients and outpatients It is economical
saving, and it does not increase the incidence
infections Skin sutures are not always nece
improving the cosmetic results It is super
ventional dressings in those sites where these a
to apply or keep in place

I wish to thank the surgeons of the Royal Free
allowing me to use this dressing on their patient
Irene Cade, F R C S, for help in the follow up

## PHILOSOPHY AND THERAPEUTI

SIR,—As a student of philosophy over m
may I comment on some of the statements
Professor Alstead in his article of Dec 25?

He asks why man is susceptible to disease whe
have been created immune to them all This is
version of the age old question "If God is all p
why did He not create the perfect man?" This
creation is hardly compatible with Professor Alstead
ment, "Most of us visualise the development
organisms through the ages as a process of gradual
Few philosophers and scientists today would d
this But the purely materialistic theory of the
which dominated the 19th century and which regard
as a mere biological accident, is becoming hard
today A number of scientists have, in our time, t
from scientific materialism to a spiritual understanding
universe more in agreement with religious belief
remarkable book *Human Destiny*, Lecomte du Nou
that science finds a purpose evident in the history
which rises above the laws of matter Since the acqu
of conscience and tradition, man can and must play
in his own destiny "Human progress therefore
du Nouy, "no longer depends only on God, but on
made by each man individually By giving man
conscience God abdicated a part of His omnipotence
of His creature and this represents the spirit of God

Disease may be regarded as one of the many h
which man has always been subjected, like death by sta
floods, marauding animals, and the more modern
of road accidents and mass warfare If he is to sur
attain to the perfect spiritual development in
with the divine plan, man must continue to rise ab
accidental environment The physician should
doubt as to the importance of his contribution to
issue by his continued fight against disease and his e
to allay human suffering wherever he finds it.

Of modern therapeutic achievements Professor
asks "If these chemical and mechanical contraptio
fact of fundamental importance in the evolvement of
destiny, why have they only now become availab
suggest that the answer is to be found in the secu
of medicine As long as medicine, science, and ph
were bound to mysticism and magic, experimentation
encouraged, in fact, it was regarded as doubting th
plan Once the scientific age was ushered in
flourished and today is the golden age of therapeutics.

C. G Eastcott H H G *Brit med J* 1954 ii 17
[illegible], K F Olow B *Nord Med* 1953 10 302

sor Alstead rightly emphasises the importance of ng the soul of man but he is very ready to sacrifice which he regards as clumsy and erratic in contrast uman mind and its activities. He makes the challeng ement that the vehicle for the spirit of man could well have been the simple amœba rather than the gly complex organism of the mammal and he hard to believe that it would matter in the slightest way of thinking the moral and spiritual development which represents the present stage in the evolutionary would have been impossible without the development human brain through the activity of which man s y and spiritual qualities are manifest How can these qualities have been developed or made manifest at utionary level of the amœba ?

pentateuch *Back to Methuselah*, Shaw has envisaged l stage of human evolution as a disembodied spirit be disembodied implies having been embodied and the man, be it ever so frail and subject to suffering and is in my opinion the only medium through which the work of evolution can be continued and fulfilled on the l plane

low Middlesex. C BEAVEN

## EMERGENCY BED SERVICE

—Early this month the Emergency Bed Service some senior members of the medical profession the operations room to see the service at work in of stress

visitors were surprised at the amount of work in hand was suggested that it would be profitable for all hospital on officers to visit Fielden House on or before their ment and thus to acquire a more vivid impression of mo of emergency cases for which admission is required don than they could by dealing only with cases in their spitals

committee think this suggestion excellent and are lad to invite all those in the Greater London area om urgent cases are offered and who have the sibility for admission or otherwise to visit the and study its work An appointment by telephone 7181) would be a great help to those in charge

Fielden House,
ondon Bridge Street,

## CONTROL OF RATS AND MICE

—I quote from your annotation of Dec 18 on this t

lay the main strong poisons of choice are zinc phos arsenic and antu (alphanaphthylthiourea)—all after ing—but antu is unsuitable for use against *R. rattus* ford workers are properly sceptical of the value of (sodium monofluoroacetate) despite the enthusiasm hich it was first received in the U.S.A

conclusions seem to me somewhat sweeping and ertainly are not in accord with our own conclusions use of rat poisons in the Port of London where, as lt of extensive field experience and investigation sons such as barium carbonate red squill arsenious and antu have been abandoned in favour of zinc ide and, more recently the anticoagulant War and the poison sodium monofluoroacetate (popu nown as 1080) Field trials are now in progre nother water soluble rodenticide which prom further useful addition to the range of rodentic o is ample evidence in this country to prove [illegible] ices of these new rodenticides in selected op[illegible] phosphide with a variety of solid bait [illegible] in with both a variety of solid bait bases [illegible] solution and 1080 as a water solution [illegible] lid bait bases While only zinc pho[illegible] in are in general use throughout th[illegible] have been proved and have been [illegible] rt of London for several years

can be dangerous if the corre[illegible] g and adequate safety precaut[illegible] but no difficulty whatever has been experienced by trained operators working in the Port of London It has proved in their hands to be a highly valuable, efficient, and readily acceptable rodenticide capable of a decisive kill overnight By its use it is also possible to secure an appreciable saving in man hours an advantage of paramount importance in port conditions where prompt action is essential It is by the selective use of zinc phosphide warfarin and 1080 that the Port of London is kept remarkably free from rodent infestation

Guildhall London E.C.2

J GREENWOOD WILSON
Medical Officer of Health,
Port of London.

## OPERATIONS ON THE HEART

SIR,—I read with interest your leader of Dec 25 and find myself in agreement with much of what Dr Cort wrote in his letter last week

Our paper[1] was concerned only with metabolic disturbances observed after mitral valvotomy Administration of saline after operation is indicated only if the patient is sodium depleted This was occasionally observed in those with mitral stenosis who had been free of œdema but had nevertheless been treated with a low salt diet and mercurial diuretics in preparation for operation After valvotomy there is an exudate from the wound and pleural cavity of fluid rich in sodium. If the body sodium content has been considerably reduced preoperatively, and this secondary loss after operation is large and uncorrected true sodium depletion may develop In such exceptional circumstances but in them alone, hypertonic saline produces a rapid and lasting improvement in both the clinical and biochemical state of the patient

The fall in serum-sodium concentration regularly observed during the first week after operation is not usually associated with a loss of sodium from the body and is certainly not an indication for giving additional saline This fall is transient and is due at least in part to water retention I do not wish to encroach on your space to discuss the wider aspects of hyponatræmia in cardiac patients apart from operation on the heart valve and should only like to endorse Dr Cort's remarks regarding hypertonic saline In patients with persistent hyponatræmia the total body sodium content measured by isotope dilution [illegible] greatly increased in spite of the low serum concentration The administration of saline simply aggravates the condition by leading to further retention of water in excess of sodium.

Sheffield G M [illegible]

## [illegible] EPILEPSY

SIR,—I think [illegible] said [illegible] Dr W[illegible] [illegible] [illegible] in his own [illegible] from [illegible] [illegible]

[illegible]

[illegible]

ond iring rtuo- s less gists in r towns ? ough work s o too much tor the general hat the broader a senior registrar in dermatology rs : I said then cialties and as strars appointed lty of acquiring who "abdominal migraine," at least while we have no method of removing the mask, and neither response to phenobarbitone nor, as yet, electro encephalography can be said to be reliable mask removers

Rapid and easy extension to cover more and more of the phenomena of ill health has always been the danger of the unifying concept, and it is only too easy to say that bilious attacks, temper tantrums, nightmares, bedwetting, obscure recurrent pains, and many other transient disorders may be due to masked epilepsy, though it is difficult to see how this helps We can try phenobarbitone in some of these cases without making a diagnosis which is likely to continue to have distressing social implications in spite of all our reassurances

Royal Berkshire Hospital
Reading

J J KEMPTON

SIR,—I was most interested in Dr Wallis's article on "Masked Epilepsy" as I believe that the condition he describes, whatever name one gives it, is not uncommon

I note that he obtains good results from treatment with phenobarbitone, but he does not mention any toxic effects from the drug I have found that protracted administration of phenobarbitone to children frequently produces behaviour disorders and irritability, and I now always warn parents about this, and if necessary use another anticonvulsant drug such as primidone

Boxhill-on-Sea

LESLIE SCOTT

## CORTISONE AND CLOSED CRUSH INJURIES OF THE HAND

SIR,—Crushing injuries of the hands in which the palmar and digital tissues are permeated by an effusion of blood and the palmar spaces are distended rank among the most crippling of injuries Treatment is long, recovery slow and incomplete, and permanent disability common

Only two cases are here presented, but their progress was so extraordinary that the matter seems worth bringing to the notice of all who are required to treat hand injuries

CASE 1—A girl of 6 was admitted to hospital after a concrete clothes post had fallen on both her hands and crushed them on a concrete slab The hands were covered with superficial abrasions and grossly swollen The palms were ballooned and tense and the fingers immobile There was no bony damage The child was shocked and in great pain The hands were moulded as far as possible into the position of function, pressure dressings applied, and the hands elevated

Six days later the abrasions were healing, but no active movement was possible and passive movement still caused pain Cortisone acetate (12 5 mg daily in divided doses) was then given for fourteen days' On the fifth day of treatment there was no pain, and far less tension and tenderness The interphalangeal joints moved actively through a full range On one side the range in the metacarpophalangeal joints was half normal, in the other it was nil On the fourteenth day of treatment there was no pain even on squeezing the hand, and the range of movement in all joints was almost full One month later, apart from very slight thickening on the back of the left wrist, two independent examiners found no abnormality

CASE 2—A man of 40 was admitted after crushing his left hand in a machine at work There was a laceration of the left thumb, and the swollen left hand resembled a blown up rubber glove, the palm being 3 in thick from front to back—about double the thickness of the right hand. No active or passive movement was possible in the fingers Under general anæsthesia the wound was excised and sutured, it did not extend into the palmar hæmatoma The hand was moulded as near to the position of function as possible and a pressure dressing applied Seven days later cortisone acetate (25 mg four times daily) was started and was continued until the total intake was 1400 mg Dressings were removed the tenth day after injury laceration healed by first intention On the eighth cortisone there was no pain on moving the fingers The interphalangeal joints moved through a full and the metacarpophalangeal joints lacked only The hand was slightly thickened

Six weeks after injury an independent exam that there was full movement in all the joints and a grip almost equal to that of the right hand. slightly reduced sensation to pinprick over the index finger

It seems impossible to explain the aston of recovery of these injuries except through the cortisone Healing of the abrasions and was allowed to proceed for six and seven days before giving cortisone, was not delayed by the used, and no side effects were observed. seems worthy of further trial

I am indebted to Dr J E Royds for his supervising the administration of cortisone.

Ashford Hospital,
Middlesex

DENNIS

## HEAT TO THE HEART

SIR,—I have read with interest Mr Picke (Jan 15) He rightly recommends the app heat to the cardiac region to allay attacks He recommends the use of a small electric handkerchief rung out of water at a 110°F

Anything hot emits infrared irradiations much more effective method of applying heat means of an infrared lamp emitting infrared black body element The heat from such a source tive, analgesic, and antispasmodic The measure by Mr Pickerill would, of course, be useful if an is not available

Experience has taught me that infrared applied for half an hour or so over the cardiac combined with a course of general ultravi diation, will greatly lessen the incidence of attacks

Eastbourne

W ANNANDALE T

## "TAKE A COUPLE OF FAT VIPERS

SIR,—Nicholas Culpeper, Gent Student in and Astrology, in the *Pharmacopœia Londi or the London Dispensatory* (Sixth Edition, 1655 two references to the medicinal use of vipers

On p 45 under the heading of "Living-Creat writes "The Flesh of Vipers being eaten (I tak English Adder to be the true Viper, though venemous as they are in hotter countries) clear help the vices of the Nerves, resist poyson exceeding is there any better remedy under the Sun for the than the Head of the Viper that bit you, bruised to the place, and the flesh eaten, you need not dram at a time, and make it up as you shall Troches of Vipers.

Referring to Troches he continues (p 268) man may make them into what form he pleas are usually made into little flat thin Cakes, of twenty grains in weight, *plus minus* some (as of Serpents upon Troches of Vipers) upon guild them with leaf Gold, some do neither

Does the expression "Head of the Viper th take chronological precedence over "the dog"?

Mile End Hospital
London E 1

W G

SIR,—I have an old family recipe for which resembles the one described last week by but which states that the chicken must be with parsley, that pimpernel and mace be adde after the viper is cut up and added, the wh rendered to one third of its original amount chlorophyll content, rather than the viper, ac its asphrodisiac reputation

Oxted Surrey

MAGNUS HAINES

## SULPHONAMIDE SENSITIVITY

-The following case of sulphonamide sensitivity usual features

tient was a married woman of 33 with no significant eases or family history She had had no previous ible except for an attack in February 1954 of sub nd facial oedema this lasted four days and cleared i histamines. No cause for it was discovered

ug 13 1954 she went on holiday to Eastbourne of recent 'flu' and nasal catarrh she was supplied e sulphadimidine tablets, and told to take 1 g every urs. On Aug 18 she returned from Eastbourne feeling well Her temperature was 101 8°F her pulse was nd a papular bullous erythema was present on all areas, with "butterfly" distribution on the face ted areas were oedematous The eruption which l rapidly was thought to be a sulphonamide sensitivity the sulphadimidine was stopped and treatment was ith promethazine hydrochloride 25 mg three times

days later on Aug 21 she was admitted to hospital r temperature was still 101°–102°F the rash was nd she had a severe cough The differential diagnosis me was (a) sulphonamide-sensitivity rash ; (b) lupus atosus ; or (c) bullous erythema multiforme

examination of the chest and blood-count on Sept 10 mal and the Q fever cephalin flocculation test was ; the erythrocyte-sedimentation rate (E.S.R.) how s 125 mm. in one hour (Westergren) An evening (up to 100–101 F) persisted until Sept 14 On the E.S.R was 57 mm. in one hour ; and serum were 0·4 g per 100 ml

pt 20 when the E.S.R was 42 mm. in one hour and nin/globulin ratio was 1 14 the patient was discharged pital By this time the rash had disappeared but is residual staining of the lesions. Marrow films l on Oct 11 for lupus-erythematosus cells were Tests for cold agglutinins were also negative

v 2 the E.S.R had fallen to 0 mm. in one hour and the elt quite well although she complained of her hair t. A month later there was still some loss of hair slight pigmentation at the sites of the original lesions. blesome cough persisted

namide sensitivity following exposure to light n This case is of interest in view of the following

sulphonamide used (sulphadimidine) is the least ll sulphonamides, and moreover it was used here in —1 g eight hourly for five days (total 15 g )

E.S.R. was exceedingly high at the onset of the illness in one hour) and it did not return to normal until ks later

one month there was an evening pyrexia (up to hich was accompanied by a cough That in associa- the high E.S.R. and the character of the rash was spicious of lupus erythematosus ; this diagnosis was excluded by the marrow smear on Oct 11 A h may be found in acute disseminated lupus osus or erythema multiforme

hair is common after sulphonamide sensitivity ultimate prognosis is good Marked residual pigmentation at the site of the lesions often persists till three months after the onset of the illness.

My thanks are due to Dr Quentin Evans and Dr H A Treble for permission to publish this case which was under their care in the Kent and Canterbury Hospital

Faversham Kent

EDWARD D FOX

## SANATORIA

SIR —Never at any time have there been sufficient beds available for the treatment of pulmonary tuberculosis in this country The result has been that one of two policies was adopted either patients were kept in sanatoria for long periods in order that quiescence might be reached with or without surgery or patients were given shorter periods of treatment and discharged non quiescent so that other patients could be admitted In the latter case the butter as it were was spread thinly over as many slices of bread as possible The experience of institutions adopting the other alternative shows that patients can be successfully treated, given time and determination by the patient and his advisers

It is my belief that bed rest like Christianity is often said to have failed when in reality the answer is that it has seldom been tried

The present comparative plethora of beds offers us an opportunity to tackle in earnest for the first time the problem of the chronic case which has so far proved insoluble except in institutions where the interests of the individual case were paramount and the shortening of a waiting list a secondary consideration

Liverpool.

D OSBORNE HUGHES

## VENEREOLOGY AND DERMATOLOGY

SIR —It is surprising that Dr Nicol (Jan 15) criticised my letter (Jan 8) without knowing the local conditions in East Kent and that he did so with so many incorrect statements

I did not plead : I commented on the possibility and the advantages of a combined post in venereology and dermatology in that particular area. Venereology was an independent specialty long before the National Health Service became effective in 1948 ; it never has been entirely separate although that is the agreed policy There is no evidence that our administrators have considered the problem solved and their policy is still to staff the clinics with experienced consultants In America, however the *Journal of Venereal Diseases* has ceased publication and at least one famous venereologist has decided to extend his interests and style himself specialist in chronic diseases.

A dermatologist recently appointed in East Anglia replaced a venereologist but Dr Nicol does not say that the retiring venereologist was also a dermatologist and that the advertisement stated that an extension of the dermatological services was envisaged. Anyhow why did these venereologists in East Anglia and East Kent elect to transfer to bigger towns ? Perhaps it supports my view that there is not enough work to hold the interest of a venereologist in some areas.

I did not say : It is a bad thing to have too much specialisation I said there was still room for the general surgeon and the consultant physician, and that the broader view was sometimes of value I did not say a senior registrar in venereology could become competent in dermatology by working in both departments for three years : I said there were many *consultants* competent in both specialties and as Mr King and Dr Russell (Jan 1) said that registrars appointed to one of the specialties had no opportunity of acquiring specialist knowledge of the other I cited one registrar who is working in both departments there are several others My registrar will appreciate Dr Nicol s congratulation but he knows that East Kent offers insufficient scope for him in venereology

With regard to local conditions, Dr Nicol will be pleased to hear that the clinics are adequate and they are well sited at the hub of transport radiations they are probably unsurpassed for accessibility in any part of the country The only major seaport in the area is Dover and that does not have busy clinics. The liaison with other parts of the hospitals was good it still will be if the appointed consultant is domiciled locally and is thereby easily available and has the broader view, it may not be so if his enthusiasm lags from insufficient work, or if he is often away on journeys to London to augment his clinical material I think, in view of the public health and social aspects of the work, that a candidate with a primary interest in venereology is desirable for the area, especially as he will have dermatological colleagues

As I see it, Dr Nicol is not clear about the position and with this letter my previous letter (Jan 8) remains to outline conditions in East Kent I am convinced that the essential requirements for that area are, as I stated, exceptional, and that a combined appointment is needed I now plead it

Seamen's Hospitals,
London
DAVID ERSKINE

## NORADRENALINE AND ESSENTIAL HYPERTENSION

SIR,—Dr Litchfield (Nov 27) finds fault with my hypothesis that excessive secretion of noradrenaline is responsible for raising the blood-pressure in essential hypertension because

(1) Hypertension may persist after the removal of a phæochromocytoma

(2) Numerous observations by von Euler and others on the excretion of adrenaline and noradrenaline in the urine have disproved my hypothesis

(3) Barnett et al.[1] found that noradrenaline infusions and phæochromocytoma could be distinguished from essential hypertension by reduction in hand and forearm blood flow and frequently by pallor of the skin and bradycardia

I shall answer these points seriatim

(1) That hypertension may persist (usually at a lower level) after removal of a phæochromocytoma is generally accepted, and, as Dr Litchfield says, "secretions of the tumour initiate another usually irreversible hypertensive mechanism" There is, however, nothing mysterious about the nature of this mechanism, it is that of renal hypertension

Excessive amounts of noradrenaline secreted by a phæochromocytoma or an overactive adrenal medulla raise the blood pressure and, in time, bring about in a certain proportion of cases a narrowing of the renal arterioles (nephrosclerosis) Since we know from Goldblatt's work[2] that renal ischæmia is the cause of renal hypertension, it is not difficult to account for the "irreversible hypertensive mechanism" found in some cases of phæochromocytoma

(2) A high urinary excretion of pressor amines has been found consistently in phæochromocytoma and is to be expected when we consider the large amounts of these substances present in the tumour Though figures comparable to these have never been found in other forms of hypertension, there is suggestive evidence that the excretion of noradrenaline may be moderately increased in essential hypertension

In 1947 Holtz et al[3] found an excessive excretion of noradrenaline in this condition (100–200% above normal) In 1952 von Euler,[4] in a study of 500 cases of hypertension, reported that excretion of pressor amines was normal in 60% and increased in the remaining 40% In 1953 Burn[5] found that the urinary excretion of noradrenaline varied directly with the age—an interesting finding when one bears in mind that the old have higher blood-pressures than the young He also showed that in a group of moderate hypertensives (mean 170 mm Hg systolic) the excretion of pressor amines was higher than in a control group of normotensives (80 µg as compared with 71 µg)

Though this difference may not be statistically significant, it may still be important in the light of the hypothesis advanced in my paper For if the level of the blood pressure is the result of a balance between two antagonistic endocrine glands and if the blood pressure lowering substance is deficient, then normal or only slightly increased amounts of noradrenaline might cause an appreciable elevation in the blood pressure In other words, normal noradrenaline figures might a relative increase vis à-vis a deficient blood pressure substance

(3) Dr Litchfield states that Barnett and his could distinguish between phæochromocytoma and hypertension by a reduction in hand and flow The question which naturally arises is how they knew they were dealing with essential hyperten pathological evidence and Goldblatt's work we t about 75% of cases of essential hypertension are by varying degrees of renal hypertension. The majority of cases of hypertensive disease the distinct mechanisms responsible for the elevation of pressure Furthermore, it is often impossible to given case of hypertension whether the mechani is renal or not, for extreme degrees of renal fa associated with a normal blood pressure, while function may be found with hypertension of origin

What is the hand and forearm blood flow in tension, in mixed essential and renal hyperten essential hypertension ? An answer to these que knowledge of the diagnostic criteria used by the would help in assessing the validity of their evidence

Barnett et al state that "essential hyper associated with a reduction in hand blood flow" and Fierst[6] do not agree In a study of 70 hyp 90 normal subjects they found that "the ave flow was much less in hypertensive than in control

Bradycardia is not at all uncommon in essent tension Normal and rapid pulse rates, however found This is best explained by postulating the secretion of varying amounts of adrenaline. F many factors unrelated to these secretions affect rate that it would be unjustifible to draw conclu this alone

A pale sallow complexion is common in essent tension As previously reported[7] this may become thyroid treatment In my limited experience of infusion (5 cases), I found that pallor appeared at ing of the infusion and also when the rate of flow w increased. When the drip flowed steadily there no pallor, suggesting that the body was adjusting stimulus In 2 cases when the blood pressure was at about 160 mm there was no pallor In 1 of t shortly after the initial pallor had passed off there flushing of both ears, which reminded me of the of Burn on the perfused rabbit's ear First a with Dutta[8] and later with Robinson,[9] he repeatedly dilator responses to adrenaline instead of the constrictor ones

It would appear then that noradrenaline hyperten occur in the absence of bradycardia and of pallor add that by stressing these details we confer o importance they do not possess We shall soon be see the wood for the trees

Finally, a word on Dr Litchfield's commen hypothesis is based on "very indirect evide a short paper designed to stress other facts possible to deal comprehensively with the Dr. Litchfield requires All one could do w briefly to the more recent developments evidence of the distant and more recent pa summarised as follows

(1) Oliver and Schafer[10] in 1894 produced a ris blood pressure by injecting an extract of the

(2) Cannon[11] and his associates demon emotions such as fear and rage were associated w pouring of adrenaline into the blood stream.

(3) Barger and Dale[12] in 1910 pointed out that of adrenaline and the effect of sympathetic tion were not always identical. They suggested differences occurred the sympathetic med adrenaline but a closely related compound, p adrenaline Cannon gave the name sympath

e responsible among other actions for vaso tion and elevation of the blood pressure

inter et al.[13] in 1948 succeeded in resolving noradrena its lævo and dextro isomers and made l noradrena- ilable for experimental study All investigators found raised the diastolic and systolic blood pressures tly It is widely distributed in the body (in all ic nerve-fibres, in the blood in the urine in the medulla and in chromaffin-cell tumours) It has been d as the sympathetic mediator in which Barger and d Cannon and his associates, were interested.

ould appear then from these facts and those ied in my paper that noradrenaline excess e or relative) is a likely cause of essential nsion

esburg PERICLES MENOF

## REINFORCING PLASTER OF PARIS

The use of 'Glassona' or cellulose-acetate glass the making of splints is familiar to most Its ar advantages are its rigidity, lightness imperme o water and transparency to X rays Of these ges the most striking, to my mind is its rigidity t. It is so rigid that the removal of a forearm cutting it down one side and springing it apart quite difficult Its particular disadvantage in the nt of fractures is the slow time of setting Excel of its great rigidity however can be made in forcement of plaster of paris If it is applied on f a plaster which has already set the disadvantage rolonged setting time is overcome, as it rests on ase and is not subject to distortion while drying

found glassona of great benefit in the reinforcement cas around the groin and shoulder spicas around the he basic plaster should be applied with moderately r so that at the time of crystallisation a fair amount of ven off If the glassona bandage is then applied after ner of a figure of eight around the groin or axilla it ut fairly quickly because of the heat of the underlying No artificial aid to drying is required and the danger of an electric drier is therefore eliminated The bandages are an excellent safeguard against cracking in or axilla and permit of the application of a lighter re permeable to X rays than would otherwise be

County Hospital DAVID P THOMAS

## NOTES ON TRANSFUSION

The Ministry of Health's booklet *Notes on ion* (1954) is being revised May I put in a plea lteration?

it is stated that if bottles of blood are punctured used within 24 hours they should be labelled ous for patients In those districts where no ies are supplied this causes difficulties When asked for and the bottles punctured for a direct is sometimes not used for example the may change his mind or the patient may die or efore the blood can be given In the area where f this happens and I label the punctured bottle fter 24 hours as dangerous for patients and then e blood for another patient my blood supply ll tell me that no blood will be sent unless I first ottle that has been sampled If I refuse to do ans either withholding blood from a patient ibly risking his life or else giving a bottle dangerous for patients

tastrophe occurred and it transpired that the l been punctured more than 24 hours before ight be infected) the pathologist would be open and perhaps to heavy damages

be argued that the statement in the booklet is d not an instruction or a directive The imprimatur title and wording suggest a directive but even if it is simple advice, when handled by a lawyer in court, it would carry great weight so it becomes tantamount to a directive

May I suggest that the Ministry bring in a non separable pilot tube as a standard fitting but until then surely in common sense and common justice the advice in the booklet should be altered

CLINICAL PATHOLOGIST

## CORTICOTROPHIN AND SPLENECTOMY IN ACQUIRED HÆMOLYTIC ANÆMIA

SIR,—It has been stated that if three or at the most four blood transfusions do not control idiopathic acquired hæmolytic anæmia splenectomy should be performed[1] While some cases fail to respond to combined splenectomy and transfusion alone[2,3] a number of authors have reported encouraging results from corticotrophin (A C T H ) or cortisone treatment[4,5] Unfortunately not all patients have benefited significantly from hormones[5,6] while in some cases an initial satisfactory response could be sustained only by continuing corticotrophin or cortisone[7] The toxic effects of these drugs may however make it impossible to continue treatment[4] and prolonged therapy followed by splenectomy may result in unsatisfactory wound healing and burst abdomen moreover a second course of hormones may be less effective than the first[5] We therefore concluded that those patients who had not improved with blood transfusion might be treated most successfully by splenectomy performed during the first course of corticotrophin We have so far treated 3 patients in this way

A male clerk aged 17 a schoolgirl aged 9 and a housewife aged 29 all presented with typical clinical and laboratory findings including pyrexia tachycardia jaundice severe anæmia, splenomegaly peripheral reticulocytosis and spherocytosis, increased red-cell fragility a positive direct Coombs test normoblastic hyperplasia of the bone marrow and increased fæcal urobilinogen excretion No abnormal hæmolysins were detected but the clerk's serum contained an auto and a pan agglutinin active at 4 C and an auto agglutinin active at 20 C in saline There was also a trace of auto agglutinin active in albumin at 4 C only The schoolgirl's serum contained auto and pan agglutinins active in saline and albumin at 4 C and a trace of pan agglutinin active in saline and albumin at 18 C The housewife's serum contained auto- and pan agglutinins active at 4 C 20 C, and 37 C in both saline and albumin

As repeated blood transfusions failed to induce a satisfactory remission in any of them corticotrophin (25 mg intramuscularly every six hours) was given for eight days in the first case and for ten days in the third case prior to splenectomy 15 mg of the hormone was given intramuscularly every six hours to the schoolgirl for five days before splenectomy Gradually diminishing doses were given after the operation for six four and ten days respectively The housewife had postoperative right basal pneumonia which responded to treatment including antibiotics This incident was followed by mesenteric thrombosis from which she recovered when treated with heparin and ethyl biscoumacetate ('Tromexan') The other two patients gave rise to no anxiety after the operation

The three patients have remained well and have led normal lives for twenty four fifteen and twenty three months respectively in spite of a positive Coombs test serum auto agglutinins and spherocytosis which persist The pan

## ISOBEL CRIPPS CENTRE

Dr RICHARD MEYER writes

Dr Barlow's assumption, in his letter last week, that this centre ignores research is incorrect Mr Neil has given me facilities to take full psychiatric histories from some of his pupils before treatment, and to follow up these people after treatment He has had the courage to take on pupils who have not responded to orthodox psychiatric or physiotherapeutic treatment I feel that his method deserves our critical coöperation, rather than destructive condescension

Mr CHARLES A NEIL writes

I wish to correct the faulty impressions given in Dr Barlow's letter

I am not teaching the Alexander technique, for although I trained with Alexander between 1932 and 1937 and owe a great deal to him and will always be grateful for what he has taught me, my methods, as a result of study of methods other than Alexander's both here and on the Continent, have undergone considerable change since 1937, and differ both in detail of theory and in technique from Alexander's

With regard to safeguards, this centre has a fully qualified medical adviser, who examines all the people who come here who are ill or suspected of illness and who are not already under medical care I do not "deal" with such conditions as asthma in the sense that Dr Barlow implies, but confine myself solely to teaching the pupil to manage his body better, and this with the approval of the pupil's doctor

# Public Health

## Maternity and Child Welfare in Glasgow

Dr Stuart Laidlaw, medical officer of health for Glasgow, reports [1] that in 1953 the infant-mortality rate (36 per 1000) was the lowest yet recorded in that city As in other parts of the country, the decline in the rate over recent years is accounted for mainly by a reduction in the number of deaths after the first month of life, stillbirths and neonatal deaths show no corresponding decrease, yet many of these, Dr Laidlaw remarks, could be prevented by better obstetric care and better education of the expectant mother Consequently he regrets that attendances at antenatal clinics once again fell Every effort was made to secure the coöperation of the general practitioners in advising expectant mothers to attend mothercraft classes and special consultant sessions at the clinics, but the response was very poor Thus, of 2479 expectant mothers who attended these sessions, only 150 were referred by their family doctors

Drawing attention to the continued need for educative work by the maternity and child welfare services, Dr Laidlaw reports that of the 58 violent deaths of infants under 1 year of age, more than half were from asphyxia following inhalation of vomit or regurgitation of food, and 23 were from suffocation by pillows, bed covers, or over laying Among children aged 1–5 accidents and violence accounted for more deaths than any other cause, accidents in the home were responsible for 7 of the 21 deaths in this group, and road accidents for another 7

Regarding mental hygiene, Dr Laidlaw reports that in Glasgow more attention is being paid to the preventive aspect of child psychiatry A special "problems clinic" has been established, at which parents are helped to resolve tensions in the child's environment and to strengthen the child to cope with difficulties which cannot be removed Cases in which definite breakdown has occurred are recognised in the clinic and  
the larger child-guidance centres. During  
patients attended the clinic, and in 32 a  
solution was reached

During 1953 the B C G vaccination camp  
extended to school-children aged 13 years.  
consent to vaccination was granted in 11,59  
11,206 children proved Mantoux-negative,  
of these received B C G vaccine In recognit  
successful campaign, the National Baby Welfar  
has awarded the William Hardy shield to Gl  
most meritorious performance in children's we  
1953

## Tuberculosis Waiting-lists in

Until 1954 the number of tuberculous  
awaiting admission to Scottish hospitals had  
fallen below 1600, between March and Septem  
year, however, the numbers fell abruptly  
to 841 This decline cannot be entirely attr  
decrease in the prevalence of the disease  
on the figures, Dr I M Macgregor,[1] of  
department of health, observes that in nearly  
"there has been no evidence of a comparable  
in the frequency of new notifications." In  
months of 1954 the number of notifications in  
and Lanarkshire was in fact 15–17% greater  
equivalent period of 1953, and even in C  
the waiting-lists show the sharpest decline,  
decreased by only 7% Assessing the  
reduction in the waiting-list, Dr Macgreg

> "More patients are now under active medical  
> their own homes supplemented by periodic visits  
> clinic Waiting lists have been purged and  
> reduced by the removal of those no longer in  
> care Although national statistics are not  
> evidence that a combination of hospital and home  
> is materially reducing the length of institutional  
> can be no doubt that recent advances in medical  
> earlier case recognition and improved housing  
> an increasing number of the tuberculous within  
> effective cure without hospitalisation"

## Smallpox in France

The French ministry of public health and  
in a message dated Jan 8, reports that the  
25 cases of smallpox in the Vannes area, with

The 1st case occurred at the beginning of D  
unvaccinated child aged 1 year The child's  
returned 10 days previously from Indo China,  
been in a hospital in which cases of smallpox  
treated All persons resident in the Vannes area  
vaccinated

A press report from Paris, dated Jan. 12,  
total number of cases as 40, including 4 dea  
departments in Brittany, the largest number  
the Morbihan department

## Statistics for England and Wales

The Registrar-General has announced [2]  
figures for the third quarter of 1954 Births  
to 15 0 per 1000 population, as against 15·6  
the corresponding quarter of 1953 The stillbir  
22 9 per 1000 total births—was 1 9 higher th  
third quarter of 1953 The death-rate was 9  
population, compared with 8 9 in the third  
1953 The infant-mortality rate—21 per 10  
live births—was the lowest yet recorded for an

The home population of England and Wales is  
to have been 44,274,000 on June 30, 1954, this is a  
of 500,000 since the last census (April 8, 1951) In  
ended June 30, 1954, persons aged 65 and over are  
to have increased by 108,000, and children aged 0–14  
persons aged 15–64 decreased in number by 20,00

In the second quarter of 1954, deaths from  
tuberculosis (1657) were 9% fewer than in the  
quarter of 1953, and deaths from cancer (21,826)  
275 more than in that quarter

# Obituary

## HAROLD WORDSWORTH BARBER

M.A., M B Camb F R C.P

H W Barber who died in London on Jan. 14 age of 68 was the first physician to be appointed staff of Guy's Hospital as a specialist in dermatology no other duties

was born in Nottingham the son of a solicitor; o was educated at nearby Repton from which he scholarship to Clare College Cambridge. In 1908 k a first class in the natural sciences tripos and years later he qualified from Guy's Hospital In he was awarded the Arthur Durham travelling ship He had by then determined on a career in dermatology, and most of his year's tenure was spent in Paris; but he also studied under Unna in Hamburg He returned to Guy's as medical registrar He was also appointed dermatologist to the Evelina Hospital and in 1915 to the Prince of Wales's Hospital Tottenham. In that year he joined the R.A.M.C and he served in India Mesopotamia, German East Africa, and France After demobilisation in 1919 he resumed the medical registrarship at Guy's, and soon afterwards he was appointed dermatologist to the hospital In 1922 he was elected F.R.C.P He served as president of the British Associ of Dermatology and of the dermatological section Royal Society of Medicine and he was consulting tologist to the Royal Navy

Elliott & Fry

his Lettsomian lectures to the Medical Society of n in 1929[1] Barber made a compelling plea for tegration of dermatology with general medicine r more extensive training of the student in this t Of the student's training he said

> it is but logical that he should be first taught to see orpret what he sees, and it is in imparting this faculty rvation and deduction that the dermatologist should chief métier in the early stages of a student's training"

e concluded:

> ignorance of the most elementary principles of the logy and pathology of the skin is it must be admitted read among our profession I believe this to be due to the fact that dermatology has been practically l in the qualifying examination and partly to faulty g of the real significance of cutaneous disorders and ns in relation to general medicine

breadth of his view is partly explained in the ing tribute from G B D:

om inclination as well as upon the advice of Cooper Harold Barber chose to study dermatology spending eater part of his year abroad in Paris under Darier hom thereafter he maintained a lifelong friendship department at Guy's he followed a line of great figures dicine in the latter half of the 19th and the early 20th ies—Addison Gull Samuel Wilks, Pye Smith and Perry Like his illustrious predecessors he possessed oundly interesting mind and for a long while he may be said to have dominated thought in British derma

He was hardly ever content to accept morphology end of knowledge even for the moment though he obably as well equipped with knowledge of that aspect matology as anyone living He communicated his ations and ideas in a large number of papers written eccable style always interesting and arresting some leaving the reader with the impression that the aries of pure reasoning had been perhaps a little pped but always providing food for thought

rber was a romantic and this was reflected in the o of his home and possessions and the beauty of his garden which he tended himself He found and enjoyed beauty everywhere in nature including human nature At the time that I knew him best he also enjoyed the simplest forms of recreation deriving almost boyish pleasure from fiction of the more exciting type from watching cricket and from following the fortunes of his often disappointing County even the bustle of a big railway terminus and a journey on a fast train gave him pleasure

With the qualities that he possessed of great erudition and enthusiasm and outstanding personal attractiveness, it was natural that he should attract to himself a large body of students of all ages who were convinced that there was no-one like Barber and never would be Inevitably the same qualities brought him an overwhelmingly large practice with its attendant responsibilities and stresses. Barber worked far too hard all his life but there is no doubt that he could like Kipling's famous tramp say at the end

So write before I die he liked it all.

Dr Barber married Juliette Louise daughter of Mme Veuve Champrenaud of Paris. There were no children of the marriage

## GLEB von ANREP

M A. Camb M D Petrograd D.Sc. Lond., F R.S

Dr Gleb von Anrep who had held the chair of physiology in Fuad I University since 1931 died in Cairo on Jan 9 at the age of 63

Though of Swedish extraction he was a typical Slav He was born in St Petersburg—practically in a laboratory for his father, Prof Basil von Anrep who discovered the local anaesthetic action of cocaine lived over his place of work. He studied medicine at the Medical Academy in St Petersburg and was still a student when he embarked on his research on conditioned reflexes.

He first visited this country in 1912 when Pavlov sent him to demonstrate to Starling the effects of vagus section on pancreatic secretion and in return to learn the technique of the preparation of secretin At the end of that year he produced his first paper in the *Journal of Physiology* in which he showed that stimulation of the splanchnic nerves liberated adrenaline from the suprarenal glands which contributed to the resulting rise in blood pressure In the following year he joined the Physiological Society

That summer he again visited London to work at University College and in 1914 he brought Babkin with him. They both returned to Russia on the outbreak of war in August. Anrep who had qualified that year served as a medical officer with the Imperial Army until Russia withdrew from the war in 1917 On his return to Petrograd he lectured for a time at the Institute of Experimental Medicine and took his M.D degree In 1918 he joined the forces of General Denikin On their defeat he made his way to England and in 1920 he was appointed an assistant in the department of physiology at University College He continued his studies and obtained the degrees of M.Sc and D.Sc of the University of London. In 1925 he was naturalised and his father joined him to live in London.

In 1920 Anrep moved to Cambridge, where he was offered a lectureship and two years later he was elected F.R.S Other academic distinctions which he received in this country before he left for Egypt in 1931 included the Sharpey-Schafer prize the William Mickle prize the Sydney Ringer lectureship, and the fellowship of University College He was also appointed to a Co Lane lectureship at Stanford University California

C L F writes: Anrep was a most attract dynamic personality—an entertaining racon lecturer, with a wide knowledge of physio elegant if temperamental experimenter capacity for work. He was a fine linguis Arabic well. During his time in Cair expert and intrepid desert explorer He Starling was only exceeded by his first master Pavlov The account reflexes which he wrote for *Rec* in 1925 was the first account of in English but he knew the the subject so intimately that in a very short time.

## GEORGE HALL

### C M G , M D Lond , B Sc Durh , F R C P , J P

Dr George Hall, formerly physician to the Royal Victoria Infirmary, Newcastle upon Tyne, died in that city on Jan 10, at the age of 76, after a long illness

He was born at Bishop Auckland, co Durham, where he received his schooling He had a distinguished academic career, graduating B SC from Armstrong (now King's) College, Newcastle, and then proceeding to his medical studies at University College, London There he won the Bucknill entrance scholarship, the Cluff prize for anatomy, physiology, and chemistry, the gold medal and exhibition in physiology, and later the Atkinson Morley surgical scholarship He obtained the London M B in 1903, the M.D in 1905, and the M.R C P in 1907 At University College Hospital he was house-physician to Dr Sidney Martin, house-surgeon to Mr Arthur Barker, and for nine months clinical assistant to Sir Thomas Barlow He then became junior house-physician at the National Hospital, Queen Square, and after twelve months senior house-physician. From this post he resigned after six months to begin consulting practice in Newcastle, and in 1908 he was appointed assistant physician to the Royal Victoria Infirmary In 1911 he was elected a fellow of University College, London

King's College, Newcastle

When war came in 1914 he was mobilised with the 1st Northern General Hospital, T A., but he left in 1915 to join the Egyptian Expeditionary Force as officer in charge of the medical division, 17 General Hospital, Alexandria For his services there he was appointed C.M G and was mentioned in despatches During 1916–17 he was officer commanding the Military Infectious Diseases Hospital, Choubra, Cairo , and in 1918 he commanded the 59th General Hospital, British Expeditionary Force, France

On his return to Newcastle he resumed the active life of a teaching-hospital physician together with consultant practice, chiefly in neurology During the twenty years that he was assistant physician at the Royal Victoria Infirmary, his chief was Dr Thomas Beattie In 1927 he was appointed physician, and in the same year he was elected a fellow of the Royal College of Physicians His interests were mainly neurological, and he was consultant neurologist to the Sanderson Orthopædic Hospital for Children He was also physician to the Ingham Infirmary, South Shields, and to the Ministry of Pensions Hospital at Dunston Hill He wrote a number of papers on general medical and neurological subjects, including one of considerable interest and importance on neuropathic keratitis He retained a warm affection for London and for University College, and examined for London University and the Conjoint Board

F J N , to whom we are indebted for some of the details, adds

" Hall was a handsome man, of quiet voice, modest but sociable equable in temperament, he was greatly liked by colleagues and students He was meticulous in the discharge of his duties gentlemanly, and cultured He loved music and helped in the organisation of the Newcastle Chamber Music Society He played a good game of golf His latter years were made lonely by the death of his wife in 1949 and by the inevitable departure from home of his son and daughter "

P H M -B first met George Hall in Egypt during the first world war

" He had that sweetness of nature, that coöperative forthcomingness which renders personal relations pleasant yet he tempered his associations with shrewdness and judgment of character I can never forget the kindness and consideration he showed as my O C at the Military Hospital at Choubra, and his counsel and help when I was endeavouring blish a clinical laboratory service This was his first with dysentery, malaria and many other exotic but he soon mastered the essentials and accorded this service first-rank importance As a successful administrator, his steady and calming influence radiated through the medical and nursing staffs, and indeed a happy ship His knowledge of medicine was and he was well versed in modern methods of but in the art of handling patients he was supreme "

F M R W *says of him*

" The death of George Hall ends a friendship of years' standing, dating from the days when we together in Egypt during the first world war I learnt to admire his clinical competence, his respect for his his wry but philosophical acceptance of the burdens of hospital administration which became his when he was charge of an infectious diseases hospital, and his integrity

" Separated by the distance between Newcastle and from those days onwards, we met comparatively seldom to meet him was always a refreshment We enjoyed our preliminary grumbles about the way things shaping in medicine and exchanged again our recollections of how much better everyone and everything when we were younger All this, of course, is one legitimate satisfactions of the elderly, is no more than the prides and visions of youth, and is compat the quiet enjoyment of life that was Hall's until the of his wife, a blow from which his spirit never recovered

" He was always a sound and conscientious physician a most unselfish and modest man, and to enjoy his was a privilege "

C E K , who became acquainted with Hall end of his career, recalls his especial affection for trained in his old hospital and his pleasure in his to a fellowship at University College

" He was not self seeking but a most kind, generous constant friend He was a modest person and his real as a man and as a physician was not immediately though in the course of time one became more and conscious of it, so that those who esteemed him most those who had known him longest His best friends old friends and I doubt whether he had any enemies "

## Royal Edinburgh Hospital for Nervous and Mental Disorders

Dr T A Munro, physician in psychological medicine to Guy's Hospital and physician to the Royal Bethlem and Maudsley Hospital, was appointed in November, 1954, to succeed Sir David Henderson as physician superintendent to the Royal Edinburgh Hospital for Nervous and Mental Disorders

Dr. Munro was educated at Edinburgh Academy and Edinburgh University and also at Harvard and Johns Hopkins Universities After a period on the staff of the Edinburgh Royal Hospital he was appointed to a Beit memorial research fellowship and worked for some years with Prof L S Penrose, F R S in the research department of the Royal Eastern Counties Institution at Colchester He has published papers on the rôle of recessive genetic factors in the production of mental disorder and of phenylketonuria During the war years he was at first in whole time charge of a neurosis centre in County Durham in the Emergency Medical Service Later he was a specialist psychiatrist in the Army at home and overseas During the last victorious campaign of the 14th Army he was consulting psychiatrist to the Allied Land Forces in South East Asia with the rank of brigadier, later being transferred to India as consulting psychiatrist to the Army in India In early 1947 he was appointed physician in psychological medicine to Guy's Hospital

## National Association for the Prevention of Tuberculosis

The Fourth Commonwealth Health and Tuberculosis Conference of this association will be held at the Royal Festival Hall, London, from June 21 to 24 The speakers will include Sister Mary Aquinas, Dr P V Benjamin, Dr M G Constantinides, Dr George Day, Dr Johannes Holm, Dr W P D Logan, Dr E L Ross, Prof Andrew Semple, Dr Honor Smith, Dr Harold Trimble, and Prof Arvid Wallgren Further details may be had from the secretary general of the association, Tavistock House North, Tavistock Square, W C 1

## International Hospital Congress

The mental well being of patients in the general hospital is to be the main theme of the congress which the International Hospital Federation is to hold in Lucerne, Switzerland, from May 29 to June 3 Further particulars may be had from Captain J E Stone, hon secretary and treasurer of the federation, 10, Old Jewry, London, E C 2

## Laboratory Animals' Bureau Congress

Sir Howard Florey, F R S, will open this congress, which is to be held at Oxford on March 28 and 29 Other speakers will include Prof J H Burn, F.R S, and Prof B S Platt Further particulars may be had from the bureau, M R C Laboratories, Holly Hill, Hampstead, London, N W 3

## International Congress for Speech Therapy

This congress is to be held in Barcelona from Sept 3 to 7, 1956 Further particulars may be had from Dr J Perelló, Provenza 319, Barcelona, 9, Spain

## Hunterian Society

The annual dinner of this society will be held at the Savoy Hotel, Strand, London, W C 2, on Thursday, Feb 10 Tickets (31*s* 6*d*) may be had from Mr R S Murley, 95, Harley Street, W 1

## Higher Rates of Insurance Benefits and Pensions

The dates from which the increased pensions and other National Insurance and Industrial Injuries benefits, provided by the National Insurance Act, 1954 (see *Lancet*, 1954, ii, 1236) will be paid have now been fixed as follows

April 25 for retirement pensions widows benefits, guardians' allowance and industrial death benefits
May 16 for maternity benefits
May 19 for unemployment benefit, sickness benefit and industrial injury and disablement benefits

The higher National Insurance and Industrial Injuries contribution rates will be introduced on June 6

Hospital inpatients, after certain periods of free treatment, receive benefits at reduced rates These reduced rates are to be increased For example, after eight weeks in hospital the benefit of patients with dependants will be reduced by 7*s* 6*d* a week, normally leaving the married couple with 57*s* 6*d* a week (instead of 47*s* 6*d* after the present reduction of 6*s* 6*d*)

---

A memorial service for Sir Alfred Howitt will be held at the Chapel of St Thomas's Hospital, London, S E 1, at 12 15 P M Jan 27

# THE DIAGNOSIS OF RHEUMATIC VALVULAR DISEASE

## 1924-1954 *

CRIGHTON BRAMWELL
M A. Camb M D Manc F R C P
SSOR EMERITUS OF THE UNIVERSITY OF MANCHESTER
CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY

-ONE before or since, has contributed so much as Coombs to our knowledge of the most important em in cardiology—the diagnosis and treatment of natic heart-disease His book on the subject hed in 1924 gave an admirably clear and authorita ccount of our views at that time Since then rer advances in radiology and in cardiac surgery o mention laboratory methods of investigation such onocardiography and cardiac catheterisation have n much new light on the picture and have consider modified our conception of valvular disease

rty years ago most cardiologists believed that the nical effect of valvular lesions was unimportant at what really mattered was the condition of the rdium. This was no new doctrine it had been the ng of George Balfour (1882) in Edinburgh and of m Steell (1906) in Manchester not to mention Mackenzie whose work, during the twenty five he practised in Burnley had convinced him that osis must be based on the patient s symptoms and the murmurs heard with the stethoscope With pinion I am sure we would all agree today but neither Mackenzie nor his contemporaries appre was that certain symptoms might be due to the mechanical effect of the valvular lesion

arding mitral stenosis Thomas Lewis wrote, in Although many symptoms may be complained patients suffering from actual stenosis, there are hat can be ascribed properly and usefully to this ity of the valve Since those words were written they are the words of one who was not only a l and accurate observer but also a lucid exponent views—we have learnt that in these cases, the nary congestion responsible for orthopnœa for rsmal dyspnœa, and for acute pulmonary œdema is y due to back pressure from mitral obstruc which can often be relieved by valvotomy with liate and remarkable benefit to the patient

noptysis has long been recognised as a common om in mitral stenosis but only in more recent as the importance of acute pulmonary œdema in ndition been fully appreciated We used to regard pulmonary œdema as a rare complication of mitral s, but now we know that this is not so It is in the most urgent indication for valvotomy My on was focused on this symptom in 1941 by two f mitral stenosis complicating pregnancy both of proved fatal The post mortem findings in these tients (Bramwell and Jones 1944) were illumin During life both had normal rhythm with a very rescendo presystolic murmur and at necropsy ere found to have severe mitral stenosis with great rophy of the wall of the left auricle This combina ggested that the rheumatic process had hit the ard, but spared the muscle Despite the extreme of stenosis the hypertrophied auricle had for years been able to maintain ventricular filling suddenly under the strain of pregnancy it failed ngs were flushed with blood pulmonary œdema ped and this rapidly proved fatal

It is in cases such as these with normal rhythm and a loud presystolic murmur that pulmonary œdema is most likely I believe the sequence of events, in such cases, is that a severe degree of mitral obstruction leads to a greatly increased left auricular pressure which in its turn calls forth a compensatory work hypertrophy in the auricular wall The powerful auricle ejects its contents with great force into the ventricle and the increased pressure gradient at the mitral orifice manifests itself clinically by the characteristic loud crescendo presystolic murmur Such hypertrophy occurs only when the auricular muscle is healthy a damaged auricle when subjected to strain fibrillates.

### Mitral Stenosis

#### THE MURMUR

Let me now refer to some of the physical signs associ ated with mitral obstruction the most important of which is the characteristic murmur

In the production of obstructive murmurs, two factors are concerned—the size of the orifice and the rate at which the blood is flowing through it. The one is static the other dynamic Further there is an inverse relation between the degree of stenosis and the velocity of the blood flow required to produce such a murmur

The influence of the dynamic factor is shown in fig 1 which is an optical record of the heart sounds and murmurs in a patient with mitral stenosis and partial heart block When we first listened to this patient s heart we were puzzled by the way the sounds and murmurs varied from cycle to cycle In the first cycle there is a loud first sound, but no murmur in the second the first sound is less loud but is preceded by a mid diastolic murmur with accentuation in auricular systole and in the third cycle where the ventricle failed to contract there is a loud murmur but no first sound The fourth cycle is similar to the first The absence of the presystolic murmur in the first and the last cycles is explained by the fact that both followed a missed beat and during the prolonged diastole preceding these cycles the auricle contracted twice When it contracted the second time it was unable to force sufficient blood through the mitral orifice to produce a murmur for the ventricle was already full During the intermission on the other hand the auricle contracted early in diastole and discharged its contents with considerable velocity into the empty ventricle producing a loud murmur The variability of the murmur in this case, was due entirely to the variation in the pressure gradient at the mitral orifice in different

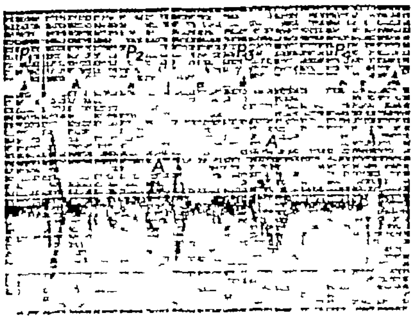

Fig 1—Electrocardiogram and optical phonocardiogram from a patient with mitral stenosis and partial A V block (This figure and the two following it, are reproduced from the *Quarterly Journal of Medicine* (1935 4 139) by courtesy of the Editors.)

* Coombs lecture delivered at the University of Bristol Nov 23 1954

57

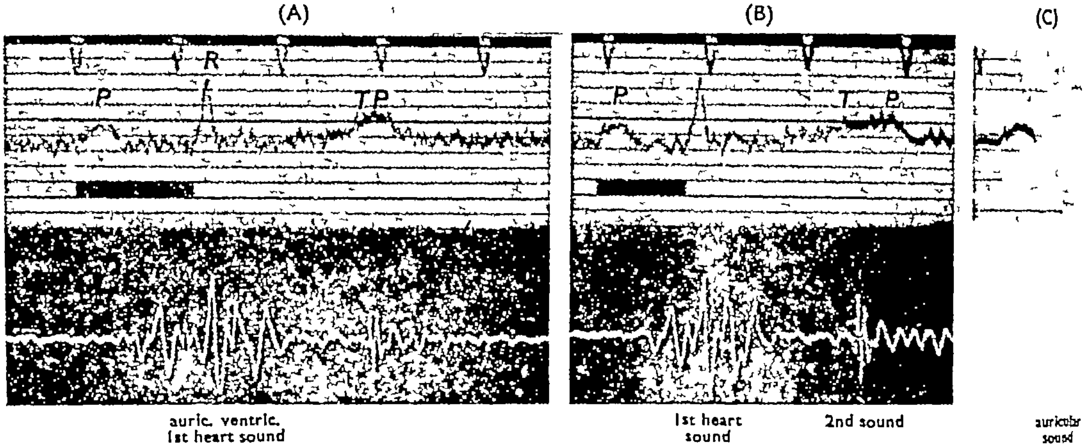

Fig 2—Electrocardiogram and phonocardiogram from a patient with partial A-V block (A) Cycle with prolonged P–R interval (B) Cycle with normal P–R interval (C) Cycle with isolated auricular contraction

cycles, as determined by intraventricular pressure at the time the auricle contracted

If the production of an obstructive murmur depends on the size of the orifice relative to the rate at which the blood is flowing through it, theoretically a murmur might be produced either by a narrowed orifice or by an increased blood flow, and we do in fact find that, in subjects with a normal mitral orifice, when the cardiac output is increased by exercise, or when the heart is overactive, as in hyperthyroidism, the first heart sound bears a close resemblance to that of mitral stenosis (Bramwell 1943) There is, then, what we might call a physiological, as opposed to an anatomical, stenosis This was clearly recognised by Carey Coombs, who stated that " A colourable imitation of a presystolic murmur is sometimes perpetrated by a normal heart acting fast "

Paul Wood (1950) has pointed out that the apical diastolic murmur heard in some patients with a patent ductus disappears when the ductus is tied This murmur is indistinguishable from that of mitral stenosis and is obviously due to an increased blood-flow through a normal mitral orifice

The reason for the crescendo character of the presystolic murmur has been a matter of some controversy Personally I believe that it is due to the final vibrations of the murmur being superimposed on, and reinforced by, the initial vibrations of the first heart sound In patients with partial heart-block, in cycles where the P–R interval is prolonged, the complete auricular complex (which is identical with the sound picture in isolated auricular beats) precedes the vibrations of the first heart sound, but, when the P–R interval is of normal length, only the initial vibrations of the auricular sound complex can be seen, the later vibrations being obscured by those of the first heart sound (fig 2)

Likewise, in patients with mitral stenosis and auricular fibrillation, when two cycles follow one another in quick succession, the murmur completely fills diastole it runs right up to the first heart sound, and, to the ear, has a crescendo character, like the auriculo systolic murmur But when diastole is longer there is a silent interval between the murmur and the succeeding first heart sound (fig 3) Under these circumstances the murmur has no crescendo termination

### THE PULMONARY SECOND SOUND

In addition to the murmurs we have been considering, there are certain other important auscultatory signs of mitral stenosis Let me refer first to accentuation and [illegible] of the pulmonary second sound

Accentuation of the pulmonary second generally attributed to increased pressure in th ary circuit, but that this is not always the true tion is shown by the fact that a loud second the pulmonary area is sometimes heard in patie pulmonary stenosis, in whom the pressure in the ary artery is lower, not higher, than normal The tion, in such cases, is that the second sound up of two components, the one due to closure aortic and the other to closure of the pulmonar The loud second sound in the pulmonary area, in with pulmonary stenosis, is due not to the pul but to the aortic component It is in fact not ac tuated pulmonary second sound that we hear accentuated aortic second sound in the pulmon Abrahams and Wood (1951) have shown that in pulmonary stenosis the pulmonary component second sound is absent

In most healthy children and young adults components can be clearly distinguished—that is the second sound is split Normally the aortic closes before the pulmonary, and in cases of incompetence, owing to the shortening of left ven systole, the two components of the second sound more widely separated (Brigden and Leatham Conversely, in patients with left bundle branch left ventricular systole is delayed and the p precedes the aortic component of the secon (Wolferth and Margolies 1935)

The split second sound is always best heard pulmonary area, and in some cases cannot be elsewhere

### THE OPENING SNAP

" Reduplication " of the second sound at has been recognised since the time of Bouillau as an important sign of mitral stenosis That tional sound was produced at the mitral orifice, not due to asynchronous closure of the aortic monary valves, was appreciated by Potain

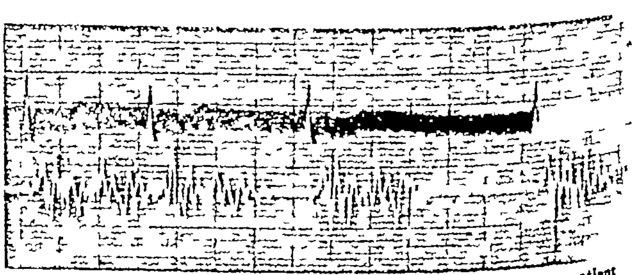

Fig 3—Electrocardiogram and optical phonocardiogram from a patient stenosis and auricular fibrillation

ave coined the term 'claquement d'ouverture de la ale' Margolies and Wolferth (1932) were able by hic records, to differentiate this 'opening snap' n the split second and from the third heart sound, and how that it was synchronous with the opening of the al valve

linically it is generally possible to distinguish the ning snap from the physiological third heart sound which I shall refer later) by its character site of imal intensity, and timing The opening snap is p and high pitched resembling in quality the second t sound, whereas the third heart sound is longer lower pitched The opening snap is usually loudest point between the apex and the left sternal border lightly higher up while the third sound is best heard the immediate vicinity of the apex The opening usually occurs earlier in diastole than the physio cal third heart sound the average interval after the mencement of the second heart sound being according to Mounsey (1953) 0 07 sec and 0 20 sec respec ly Unfortunately as Wood (1954) has pointed out, dvanced mitral incompetence the third sound may ome much more like an opening snap in that it may ess delayed and much sharper and higher pitched n usual

ellors and his colleagues (1953) believe that the ening snap is due to sudden tension of the mitral e as it balloons upwards into the ventricle at the t of diastole and consider that it is a reliable sign of re mitral stenosis with a pliant diaphragmatic type valve It is absent when mitral regurgitation is dominant and when the valve is much calcified (Wynn ) and for these reasons it may be regarded as a urable indication for valvotomy

ikewise Sellors and his colleagues think that the racteristic snapping first sound (which they call the sing snap') is due to sudden tension of the pliant al diaphragm as it bulges into the auricle at the nning of systole This closing snap can be palpated ell as heard In the words of Carey Coombs The l placed over the precordium feels the apex bang lenly and sharply against the chest wall then sink y from it as suddenly as it arrived

## THE THIRD HEART SOUND

gallop rhythm, three instead of two heart sounds mpany each cardiac cycle the additional sound t due to rapid distension of the ventricle When the ional sound is synchronous with auricular systole convenient to call it the fourth heart sound (Evans ) to distinguish it from the third heart sound which s early in diastole

here are three types of gallop rhythm of clinical rtance—protodiastolic, presystolic and summation p (fig 4) In protodiastolic gallop the additional d is an accentuated third heart sound, in presystolic p it is the fourth heart sound and in summation p it is a combination of the two for when the heart ting quickly auricular systole falls in early diastole the result that the third and fourth heart sounds ide

systolic and summation gallop do not concern us but protodiastolic gallop merits careful considera for it occurs in normal subjects as well as in patients mitral disease

yer (1908) found that a third heart sound was le in 68% of healthy young persons He also nstrated experimentally in dogs a similar sound corresponded in time to the sudden distension of entricle th[illegible]rred early in diastole and he ested that [illegible] heart sound was due to the n rush o[illegible]om auricle to ventricle when itral valv[illegible]ns

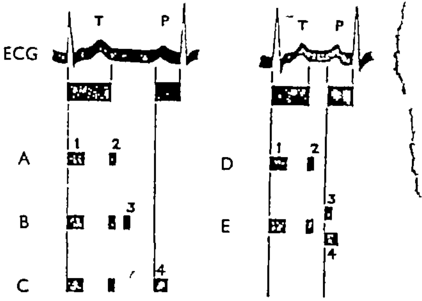

Fig 4—Diagram to illustrate different types of gallop rhythm. (A and D) Normal rhythm. (B) Protodiastolic gallop (C) Presystolic gallop (E) Summation gallop. 1 2 3 4 First second third and fourth heart sounds. The large rectangles immediately below the electro cardiogram represent ventricular and auricular systole.

So many apparently healthy recruits were referred to me during the war by the Ministry of Labour and National Service on account of a third heart sound that I decided to investigate the matter In a consecutive series of 832 recruits examined a third heart sound at the apex was heard in 151 This series did not include any case in which a diastolic murmur could be heard or a presystolic could be elicited exercise

The incidence of the physiological third heart sound is greatest in young subjects. It was present in 43% of men under 20 but in only 10% of those over that age

In mitral regurgitation the rate of ventricular filling is increased This favours the production of a third heart sound Severe stenosis has the opposite effect Hence in patients with mitral disease there is likely to be an opening snap but no third heart sound when stenosis predominates but a third heart sound and no opening snap when incompetence is the dominant lesion

I cannot leave this subject of mitral stenosis without referring to the murmur of pulmonary incompetence associated with the name of my old teacher Graham Steell Steell's (1888) original description of this murmur which he called "the murmur of high pressure in the pulmonary artery' was a masterpiece of clinical observation He drew attention especially to the variability of the murmur from day to day and to its constant association with a greatly accentuated pulmonary second sound

The Graham Steell murmur is now accepted by all cardiologists but the same cannot be said of the Austin Flint (or what a candidate I examined in Membership called the Austin Reed murmur! It wasn't till I asked him who Austin Reed was that I thought I could perceive a faint flicker of activity in a remote corner of his temporal lobe )

The original description of this murmur (Flint 1862) was based on two cases of aortic incompetence in which an apical presystolic murmur had been audible during life but no disease of the mitral valve was found at necropsy Flint suggested that the regurgitant stream through the aortic orifice impinged on the aortic cusp of the mitral valve and brought the leaflets of the valve into apposition causing a functional stenosis of the mitral orifice Paul White (1926) put forward the alternative hypothesis that the murmur was due to relative stenosis of the mitral orifice following dilation of the left ventricle Some workers however including Warburg (1946) and Luisada (1944) are doubtful whether such a murmur ever occurs and Carey Coombs himself appears to have been of that opinion He wrote In very few [illegible] indeed does there seem to be incontrovertible of the Flint hypothesis.

### Mitral Incompetence

No valvular lesion has had quite such a chequered career as mitral incompetence Those who served in the first world war were well acquainted with "V D H" (valvular disease of the heart) and "D A H" (disordered action of the heart) These two terms made cardiology delightfully simple If you heard a murmur it was V D H , if you didn't, it was D A H Now V.D H was organic, but D A H was functional , so, if a man had V D H he had to be invalided out, but if it was only D A H he could be cured and returned to duty ! The diagnosis of V D H was perhaps not quite so fantastic as might appear at first sight , for we were dealing with young men, and the only common types of heart disease in this age group are rheumatic and congenital, both of which generally manifest themselves by murmurs Coronary disease and hypertension do occur, but they are exceedingly rare at this age Where this diagnosis came to grief was the failure to recognise that heart murmurs might be due to causes other than valvular disease

Graham Steell (1906) gave credit to his "master," George Balfour of Edinburgh, for being the first to point out that, in chronic "mitral disease" the condition found post mortem was commonly mitral stenosis, not structural damage to the valves producing incompetence without stenosis Steell states that, at that time, the terms "mitral disease" and "mitral incompetence" were practically synonymous Balfour (1882) had realised that mitral regurgitation was not necessarily due to a damaged valve, and had coined the term "curable mitral incompetence" for the systolic murmur heard in cases of chlorosis—a murmur which disappeared when the anæmia was successfully treated

Steell himself emphasised the fact that muscle contraction was an essential complement of the valvular apparatus In his own words, "No mitral valve can be competent if it fails to receive that assistance from the heart muscle it is designed to receive in the performance of its function" He added "Such destruction of the mitral curtains as would alone cripple their function (without there being mitral stenosis) is almost limited to cases of septic endocarditis" To this last statement I shall refer again later

Regarding this point, Carey Coombs wrote "An apical systolic murmur is certainly an indication of mitral incompetence , but, unless the bruit be long, loud and high pitched, it does not prove that the incompetence is due to endocarditis and it should be attributed to muscular rather than valvular disease"

Nevertheless in 1914 this lesson had not been driven home, and, in the first world war, many doctors had still to learn that a heart murmur did not necessarily mean valvular disease

Between the two wars, the pendulum swung in the opposite direction—obviously too far Some cardiologists of this period seemed to regard the diagnosis of "mitral incompetence" as hardly decent ! Lewis (1933) wrote "There are no symptoms to be attributed to mitral regurgitation The only sign that can be named is a systolic murmur" Cabot (1926) in his fascinating book *Facts on the Heart*, in which he correlates the clinical with the post mortem findings, recognises that mitral incompetence may occur, but concludes that a diagnosis of mitral regurgitation without stenosis is never justified

Freeman and Levine (1933), on the other hand, believed that loud apical systolic murmurs were generally due to mitral disease, and both Fishberg (1940) and Master (1948) held that the importance of apical systolic murmurs had been underestimated

The successful intervention of the surgeon in the treatment of mitral stenosis gave a new lease of life to mitral incompetence , for, although rheumatic mitral [illegible] ce without stenosis is rare, a combination [illegible] s common, and in assessing the suitability of a case for valvotomy it is important to know wh predominant

We now base the diagnosis of mitral regurgit chiefly on three signs (1) a loud apical systo (2) dilatation and hypertrophy of the left ven which is recognised clinically by the heaving su apical impulse, and radiologically by the charac changes in the cardiac silhouette described by P (1949) , and (3) expansile pulsation of the left synchronous with ventricular systole This can b in the postero-anterior as well as in the right o position, and must be distinguished from bac displacement of the left auricle by a hypertroph ventricle, which may occur in pure mitral stenosis sign is not always present Confirmatory evidence be obtained from the pulse, which in mitral incomp is of full volume as contrasted with the small pulse of pure stenosis

Nevertheless, as Baker and his colleagues (1959 pointed out, despite these various diagnostic cr unsuspected free mitral regurgitation is occa revealed at operation

Douglas and Hill (1954) compared the clinical ment of mitral incompetence with the operative In 26 cases in their series there was close agreement 5 cases mitral incompetence was suspected but stenosis was found at operation , while in 15 case degree of mitral incompetence was underestimated

BACTERIAL ENDOCARDITIS

I have already referred to the association of pure incompetence with bacterial endocarditis This as tion is well recognised, but has never been satisfac explained Of Brigden and Leatham's (1953) se 30 cases of pure mitral incompetence, 10 had ba endocarditis , and of my own (Bramwell 1948) se 12 cases of bacterial endocarditis with mitral that came to necropsy, mitral stenosis was pres only 2 So rarely does one hear a typical cre presystolic murmur in patients suffering from b endocarditis, that its presence is sufficient to m question the correctness of the diagnosis

These facts cannot fail to raise in one's mind whether the orthodox view that subacute ba endocarditis rarely attacks a heart not prev damaged by rheumatic infection, or the seat of congenital abnormality, is correct , for it is rem that the pre existing heart disease is almost trivial, and that patients with advanced heart appear to be relatively immune For example, au fibrillation was present in only 5 of Cates and Ch (1951) 269 cases Likewise of the 33 patients in r series, none gave a history of heart-failure before tion, and in only 3 had there been any con impairment of capacity for effort

Some observations by Carey Coombs have an tant bearing on this subject In 1923 Coombs re 30 cases of "endocarditis lenta" seen since the e first world war He distinguished "endocarditis from the more acute type of bacterial endocar the facts that it runs a course of many months years (one of his patients lived for over three that there is little or no fever, and that necrops anatomical evidence of stubborn opposition infection

Of his 30 patients, 29 were males, of whom served in the Army, and of these 80% had been men or gunners, with an average period of se more than three years, mostly in France Coor that, with only one exception, they were "me physique and morale, men who joined the arm served with all their might, and [illegible] them the utmost limit of their physical [illegible]" Br he did not encounter a single case among men of ysique whose service had been at the base and ere at home or overseas He concludes that So nt is the relation/between physical fitness and ous exertion on the one hand, and proneness to rdial infection on the other that a belief in the relation between the two can hardly be avoided ggests that excessive fatigue from the strenuous on to which these men had been subjected may redisposed the body to infection It is indeed hard eve that these men had any pre existing valvular

## Aortic Stenosis

views regarding the diagnosis of aortic stenosis been profoundly modified in recent years

### SYMPTOMS

1933 Thomas Lewis wrote ' There are no symp of aortic stenosis. ' It is interesting to compare this nent with that of King nine years later (Bramwell ing 1942) He wrote

> tients with this condition are liable to the usual symp- f cardiac disease and in addition they frequently show e of cerebral anæmia Angina may occur Sudden n is poorly borne and may be followed by sharp dyspnœa ncope When the heart begins to fail the progress is persistently downhill regardless of therapy The r very often proves fatal during the sixth decade later stages, mild mental symptoms are common : lity extreme drowsiness and delusions

surprising how many of these patients remain free symptoms until the sixth or seventh decade in of having led active lives Not infrequently a ur had been noted many years previously This l picture which has been well described by David (1951) does not seem to have been familiar to ians in the past. Lewes s paper is based on 25 of calcareous ' lone aortic stenosis verified post n (i.e., cases in which aortic stenosis was the only ant valvular lesion)

age at which symptoms develop in these cases ts that they are not directly due to the pre-existing ar lesion which may be of long standing but to degenerative changes superimposed upon it have transformed it from a benign to a malignant ion just as subacute bacterial endocarditis may rimposed upon rheumatic mitral or aortic valvular

mechanism of syncope in these patients has not nally established : it differs from ordinary vagal o in that it is usually associated with effort and respect it resembles angina of effort Moreover ersten (1951) found that, in patients with severe stenosis who developed syncope cardiac pain was more common than in those who did not Likewise and Bean (1948) found that sudden death in s with aortic stenosis was most common in those lso experienced cardiac pain This apparent tion between syncope and sudden death on the nd and cardiac pain on the other suggests that ay be due to the same cause—namely myocardial ia—a hypothesis which receives support from ersten s further observation that of patients with stenosis those who develop syncope have larger and so would be more liable to ischæmia than who do not Contratto and Levine (1937) have l out that in these cases cardiac pain may occur ndently of aortic incompetence or coronary

s been shown by Tennant and Wiggers (193[illegible] hat myocardial ischæmia leads to a dim[illegible] output and Hammersten suggests acc[illegible] ncope may be due to cerebral anæmia [illegible] iminished cardiac output secondary to m[illegible] ia

### PHYSICAL SIGNS

Regarding diagnosis Thomas Lewis wrote

> The outstanding diagnostic sign of aortic stenosis is a small pulse rising slowly to a delayed summit : the condition should never be diagnosed without this sign The second sign is a systolic thrill at the base of the heart usually maximal at the second right cartilage or space

Our diagnostic criteria are now much less rigid than they were then for Wiggers (1944) has shown that it is not until the aortic orifice is reduced to a quarter of its normal size that the form of the pulse is modified in the manner described by Lewis It is therefore hardly surprising that this sign is present in less than half the cases. Even in severe stenosis, the pulse may be full and collapsing and in about half the cases there is some associated aortic incompetence

A loud harsh basal systolic murmur is the commonest sign in these cases , in fact it may be the only sign The murmur, however is not always loud , and, unless it is loud, there is no thrill Moreover the murmur is often well heard not only at the base but also at the apex and occasionally is loudest in that area in which case it may not be easy to decide whether it is due to aortic stenosis or to mitral incompetence for both lesions give rise to left ventricular enlargement, and in both the pulse may be of full volume Under these circumstances, as Leatham (1951) and others have shown the shape of the systolic murmur and its relation to the heart sounds in the phonocardiogram may be helpful in diagnosis In aortic stenosis the systolic murmur [illegible] shortly after the first sound and rises to a max[illegible] mid-systole It then diminishes rapidly [illegible] before the second sound In mitral incomp[illegible] other hand the murmur fills the whole of [illegible] immediately after the first sound and [illegible] up to the second sound which may be [illegible] the apex if the murmur is loud

Absence of the aortic second sound [illegible] able importance in diagnosis has [illegible] been attached is evidence of advanced [illegible] but as Parkinson and Hartley (1946) [illegible] a normal second sound does not exclude the [illegible]

Parkinson (1949), in his Ca[illegible] empha sised the value of fluoro[illegible] of this lesion It reveals n[illegible] of the left ventricle but also calc[illegible] of the aortic valve Tomography can also be [illegible] calcification (Davies and Steiner 194[illegible] was present in 26 of the 32 cases [illegible] to and Levine (1937)

Campbell and K[illegible] find any consist[illegible] relation in their cases [illegible] of the [illegible] second sound [illegible] of the valve [illegible] in

Another [illegible] fluoroscopy the [illegible] tance of which has been emphasised by Kiloh (19[illegible] with others [illegible] ascending aorta [illegible] others in the [illegible] 1949) also [illegible]onchiectasis

### [illegible]TIOLOGY

[illegible] of calcific a[illegible] d proved and [illegible] divided Kar[illegible] and 4 2% of (19[illegible] monograph [illegible] 11 children [illegible] came to the [illegible] unsatisfactory [illegible] always rheu[illegible] ho eventually [illegible] strongly [illegible] minate [illegible] 1921 1936) [illegible] non-specific [illegible] He Kiloh [illegible] aortic stenosis [illegible] of age wa[illegible] rheumatic [illegible] aortic sten[illegible] incompetence or [illegible] this view pathological as well as clinical, points to the extreme rarity of aortic stenosis as a result of rheumatic infection "

Rheumatic carditis generally leads to stenosis of the mitral valve, but to incompetence of the aortic valve, and I would suggest that the reason for this is purely anatomical the cusps of the mitral valve spring from a continuous curtain, so, when cicatricial contraction follows inflammation, they tend to be drawn together, whereas the cusps of the aortic valve are discrete, and so tend to be drawn apart

When calcification supervenes in a case of pure aortic stenosis, the valve may become incompetent, but, in rheumatic disease of the aortic valve, stenosis is secondary to incompetence

The sex-incidence of calcific aortic stenosis (males being affected much more commonly than females), its benign course over a long period of years, the rarity of a history of rheumatic infection, and the fact that it is hardly ever associated with a mitral lesion, are all strongly opposed to the idea that the condition is rheumatic

In a recent paper, Campbell and Kauntze (1953) point out the difficulty in arriving at a histological diagnosis in cases with scarred and calcareous aortic valves, and consider that the ætiology may be more accurately assessed from the history, progress, and physical signs than from necropsy material They believe that pure aortic stenosis under the age of 30, is more likely to be congenital than rheumatic In 20 of their 40 cases, the heart murmur was noticed in early childhood, generally before the age of 4, and many of their cases were referred to them with a diagnosis of congenital heart disease

Campbell and Kauntze make the interesting observation that many of these patients, like patients with coarctation of the aorta, have outstandingly good physique

Compared with the other three valvular lesions we have been considering, aortic incompetence has attracted very little attention during the past thirty years in fact I think it would be true to say that Corrigan's (1832) original description of the clinical picture has scarcely been modified by subsequent work

## Conclusion

My aim here has been to review certain aspects of the changing picture of rheumatic valvular disease

The remarkable advances which we have witnessed in cardiac surgery in recent years have aroused a new and lively interest in mitral stenosis, and improvements in phonocardiographic technique have enabled us to record with greater accuracy what we hear with the stethoscope Just as electrocardiography, by depicting the various types of arrhythmia, enabled us to recognise them by the unaided senses, so phonocardiography is teaching us to distinguish, by auscultation, between the different sounds and murmurs heard in health and disease

In the period between the two world wars, mitral incompetence was regarded by most cardiologists with remarkably little respect since the introduction of mitral valvotomy, however, its importance has been universally recognised, though its clinical recognition is not yet always possible

The radiological diagnosis of valvular calcification has widened our concept of aortic stenosis, but the ætiology of this condition, and the mechanism of production of some of the symptoms associated with it, are still undetermined

# PULMONARY PRIMARY TUBERC IN CHILDHOOD

C H M Walker
M.D Edin, M.R C P., D C.H.
SENIOR REGISTRAR TO THORACIC UNIT, THE HOSPITAL F
CHILDREN, GREAT ORMOND STREET, LONDO

THE belief that the prospects of all childr healed primary tuberculosis are universally go been questioned by Holmdahl (1950) in Scandin only a long-term follow-up will tell whether or th same prognosis holds good for this country Th is the preliminary report of such a follow up R publications by Bentley et al (1954) and Holmdahl are accompanied by comprehensive bibliographies need not be repeated here extensively

## Material

The number of children examined in the pres was 767, comprising 719 examined in the outpatient clinic and in the wards of the Hospital f Children, Great Ormond Street, and 48 seen at U College Hospital, London This number does no sent all the Mantoux-positive children atten hospitals but only those whose clinical picture tuberculosis and who were radiographed because Of these, 102 were considered to be no longer " judged by general condition, erythrocyte-se rate (E S R ), and radiological appearances In 53 the site of the primary complex could not be dete and 34 showed evidence of non-pulmonary These were all excluded from this analysis, lea cases in which there was adequate evidence of a primary tuberculous complex in the lung wh examined This unfortunately cannot be regar truly random sample of patients with this co

se there was, in the early days of streptomycin y a high admission rate of children with tubercu eningitis sometimes in the later stages Some such en were admitted from other hospitals and others eferred by general practitioners and tuberculosis or were diagnosed in the course of general medical ient work It is realised also that hospitals of this of necessity see more ' complicated ' cases than a act' or tuberculosis chest clinic

number of cases included in each analysis varies ding to the information available the duration of up and the type of treatment Any particular on is explained in the appropriate section

### Complications of Primary Complex

he 578 cases 40 were omitted from this analysis e of inadequate documentation Half of the ing 538 children were followed up for two years re, and rather less than a half of these are still observation About 20% (106) were followed e or two years and 12% for from six months ear This leaves only 18% of the children who ollowed up less than six months They include se, most of the 55 who died and since relatively hers were followed up so short a time the analysis below of the complications which may follow the ary primary complex must be fairly accurate I)

*ntal Lesions*

workers agree that the most common compli of the primary complex is the segmental lesion adiologically yet the incidence of this finding widely in different reports Macpherson and che (1950) report a collapse incidence of 4.7% y et al. (1954) and Roberts and Blair (1950) 19% hompson (1952) 28% Such differences are not rising when one considers for example that Miss erson's cases come from a contact clinic and Dr y's from a residential institution. One might the more severely complicated cases to be admitted pital treatment and thus an unavoidable selection s is made.

s been found also that the age of onset has some on the frequency of collapse Richards (1944) that 21% of 239 children aged less than 6 years llapse due to bronchial obstruction and only f children aged more than 6 years

other possible explanation for this discrepancy found in the interpretation of the radiological tal shadow Adler and Richards (1953) think llapse and consolidation can be distinguished gically, but most workers find this distinction if not impossible What exactly is meant by rms as epituberculosis and flare is uncer d the criteria for the selection of a specific lesion collapse are difficult to establish Epituberculosis a diagnosis we no longer recognise and because confusion of nomenclature and difficulty of inter n the remaining group of collapse consolidation called hilar flare have been classified under one in the present series It is fully realised that in re must have been caseating pulmonary lesions and this has been borne out by the later appear calcification in the lung parenchyma or by ny specimens On the other hand, the gradual of an obstructed bronchus confirmed by repeated scopy and a coincidental clearing of the radio- shadow were seen often enough to convince us lapse is the main feature in most cases

therefore because of this classification and the ty of the cases that the incidence of this seg lesion is as high as 48.3% (260/538) in this series re differs strikingly from the over all incidence of suggested by Bentley et al. (1954)

TABLE I—COMPLICATIONS IN 538 CHILDREN

| Complication | Age at onset (yr) | | | Total |
|---|---|---|---|---|
| | 0–2¹¹/₁₂ | 3–5¹¹/₁₂ | 6–12 | |
| Collapse consolidation &c. | 96 | 98 | 66 | 260 (48.3%) |
| Local dissemination | 12 | 7 | 6 | 25 (4.6%) |
| Proved bronchiectasis | 1 | 5 | 5 | 11 (2.0%) |
| Pleural effusion | 3 | 9 | 16 | 28 (5.2%) |
| Meningitis | 19 | 16 | 6 | 41 (7.6%) |
| Meningitis and miliary tuberculosis | 10 | 14 | 6 | 30 ([illegible]) |
| Miliary tuberculosis only | 13 | 5 | 4 | 22 (4.1%) |
| None | 48 | 53 | 64 | 165 (30.7%) |

*Local Parenchymatous Dissemination*

This may well have been present in some cases, but definite radiological evidence was only obtained in 10 of the survivors the total incidence being 4.6% (25/538) We came to regard this complication along with cavitation and bronchopneumonia with some trepidation because the mortality rate in the lowest age group (0–2 yr 11 mos ) was about 60% Among the survivors there were 5 in whom cavitation was observed but it has been suggested that more frequent tomography would reveal a greater incidence of this complication (Heaf 1953) The necropsy figures of Bentley et al. (1954) add weight to this suggestion

Most workers—e.g Hardy et al 1952 Daly et al. 1952 Lowys and Larmoyer 1953 Carlens and Hellström 1953 Adler and Richards 1953—find endobronchial disease in about half the cases bronchoscoped with fistulæ less often observed and the results in the present series are no exception The bronchial wall was breached and the lumen encroached on by caseous material in 20 of 44 children bronchoscoped It is therefore perhaps surprising that bronchopneumonia is rare occurring only three times amongst the survivors and eight times in 58 necropsies Gemini and Rickler (1952) consider that most fistulæ heal without spread of tuberculosis

*Obstructive Emphysema*

This developed in only 7 children and is particularly mentioned because at first this complication of hilar adenitis may be missed It is usually associated with particularly large glands which have ulcerated through into the lumen of the bronchus Stridor is often a prominent symptom, and bronchoscopy may give considerable relief

*Bronchiectasis*

The development of this complication has always figured largely in published reports and in this country Roberts and Blair (1950) Jones et al (1940) and Hardy et al. (1952) have reported an alarmingly high incidence 60% 70% and 71% respectively of children with segmental lesions were found to have bronchiectasis in most cases confirmed by bronchography Daly et al (1952) however found only 1.1% of 434 children with tuberculosis had proved bronchiectasis but 18 others were suspected of having it Hutchison (1949) also found a low incidence 2 cases developing bronchiectasis out of 30 showing collapse

In the present series 11 children had proved and persistent bronchiectasis—i.e. 2% of 538 and 4.2% of the children with segmental lesions Of these 11 children 5 were among the 7 whose progress was unsatisfactory whose lesions persisted for years and who eventually underwent lobectomy This may be an underestimate and more cases may manifest themselves later but there is good reason to believe that the early bronchial dilatation associated with segmental collapse is reversible If bronchography is done early in the disease while collapse is present a high incidence of bronchial dilatation may be expected but good filling of the bronchial tree may at this stage of the disease be difficult. Even though some dilatation remains after re-expansion it is usually symptomless (Jones et al 1940 Williams and Anderson

TABLE II—DEATHS (INCLUDING NON-PULMONARY PRIMARY CASES)

| Complications | Age (yr) | | | | | |
|---|---|---|---|---|---|---|
| | 0–2¹¹/₁₂ | | 3–5¹¹/₁₂ | | 6–12 | |
| | No of cases | No of deaths | No of cases | No of deaths | No of cases | No of deaths |
| Tuberculous meningitis | 19 | 11 (*58%*) | 19 | 6 (*32%*) | 6 | 1 (*17%*) |
| Tuberculous meningitis and miliary tuberculosis | 22 | 16 (*73%*) | 14 | 11 (*79%*) | 9 | 5 (*56%*) |
| Miliary tuberculosis | 14 | 6 (*43%*) | 8 | 0 | 5 | 1 (*20%*) |
| Total | 55 | 33 (*60%*) | 41 | 17 (*41%*) | 20 | 7 (*35%*) |

1953), and it is for this reason that bronchography was not done more often in children with segmental lesions Until a few years ago bronchograms were done simply to confirm the presence of bronchial dilatation Latterly, however, they have been done only if the children have remained ill and have shown persistent physical signs for two or more years These children are among the important few who eventually require operation, and up to date 5 of the 11 children with proved bronchiectasis have had lobectomies Altogether 39 children showed suspicious bronchial markings on straight radiography, and 16 of them underwent bronchography 10 showed dilatation, 5 showed a normal bronchial tree, and in 3 the procedure was unsuccessful Most of these children showing some crowding of the bronchi and suspicious dilatation were radiologically normal in about two years, but it seems that those who have abnormal bronchograms after this time are likely to require surgery In addition to the 5 who have already had lobectomies, at least another 2 will probably require surgical treatment

*Pleural Effusion*

As might be expected, half (57%) of the 28 children with this complication were in the oldest age group (6–12 years), but 3 cases occurred in children aged less than 3 years, and 12 in children aged less than 6 years

There have been reports that the ultimate prognosis of tuberculous pleural effusion is considerably worse than that of the simple primary complex (Bentley et al 1954, Smithers 1934), and that children who develop their effusion after the age of 10 years have higher morbidity and mortality rates than the younger patients (Nathorst 1948) The long-term follow-up of these 28 children may be of some further value in this respect

*Miliary and Meningitic Tuberculosis*

These were the most serious complications and either separately or together accounted for most of the deaths in this series (table II) There were 102 cases (19%) The incidence of these conditions alone or in combination is seen in table I Of 61 children with miliary tuberculosis more than half developed meningitis, and, as in the investigation of 100 deaths by Bentley et al (1954), there were about the same number of cases of meningitis with as without miliary disease Again, as one might expect, the incidence of meningitis is highest in the lower two age-groups—i e, less than 6 years—though miliary tuberculosis alone was much more often found in the children aged less than 3 years

It must be emphasised again that the incidence of these serious complications is high partly because the cases admitted to hospital are a selected group, but the proportions within this group can probably be regarded as true estimates for hospital practice as a whole

*Miscellaneous Complications*

To complete the picture the following complications mentioned, if only to indicate what diverse results may ensue through a restricted hæmat spread subcutaneous abscesses, dactylitis, spinal arthritis of the hip, lupus, skin tuberculides, ma and tuberculoma We have been impressed b late after the active phase of the primary comple tuberculosis can develop, and how easily the earl of such a severe condition as spinal caries can be

Phlyctenular conjunctivitis (unlike erythema n which is seen only in the early phase) has been at all stages of activity of the primary comp in 1 case the pressure of an enlarged gland phrenic-nerve palsy

### Bacteriology

The isolation of the tubercle bacillus is still and chancy The advances in homogenising such examination have unfortunately little bea pædiatric practice, and the Ministry of Health has pointed out how important is the lab nique With the advent of B C G the finding bacillus has become more important, and it appointing to find such a high percentage of results in children known to have primary tub This is not really surprising, since the primary is virtually a closed lesion, unless there parenchymatous spread or ulceration into a

The results of bacteriological investigations cases are shown in table III If the figures for th and adenoids are excluded, positive results we in only 16% of examinations (25/152) This at fi seems to compare unfavourably with the 30% of Bentley et al (1954), till it is realised th patients included adolescents and a greater

TABLE III—BACTERIOLOGY

| Source | Age (yr) | | | | |

| Tonsils and adenoids together | | 10 | | 10 | |

patients with chronic pulmonary tuberculosis, fro sputum is more easily obtained The perc positive gastric washings in their cases and in th series, however, is the same—about 22% T comparison might be expected because gastr would be used in children of much the same age a similar clinical picture in the two group examination of pleural fluid and stools reward, the discovery of the tubercle bacillus closely related to the availability of sputum sputum is obtained, however, there is still chance of isolating the bacillus, even in older chi adolescents

The tonsils and adenoids were removed in 64 reasons which include chronic nasal discharge, infection of the upper respiratory tract which with the child's general progress, sometimes phlyctenular conjunctivitis, and because examination showed that infected tonsils and could keep the E S.R raised and delay the heal chest lesion

The tonsils often looked unhealthy, but tonsils just as often look innocent (Browne 1952) In no case was there tuberculous cervical yet in 17 (26%) of 64 examinations of tons adenoids evidence of tuberculosis was seen on examination Browne and Hall (1952) found the

ere obtained from the tonsils and adenoids in third of the active, and in none of the inactive primary tuberculosis of the lung In the absence l adenitis it is likely that the tonsils and adenoids ondarily infected by tubercle bacilli from the l secretions If there is chronic infection of the spiratory tract the removal of the tonsils and is probably justified because there is a 1 in 4 hat these may act as a source of continued with tubercle bacilli

## Source of Infection

the 578 children had a history of contact with case of tuberculosis 29 of them having had contacts (table IV) The remaining 260 children uch history and only very few of these had no f the question having been asked. Over half lren (54%) therefore had a tuberculous contact er (not the mother as might be expected) being common positive contact It is not surprising the highest contact rate in the youngest age- nd Bentley et al (1954) go so far as to say that is an inverse relationship between age and history tant contact

## Bronchoscopy

workers agree that as a therapeutic measure, scopy has not often been a success, and only rt (Margolisowa 1953) could be found in which sion occurred in most cases There are a few indications however and these include (1) collapse particularly involving the lower lobes spected suppurative lesion distal to bronchial ion (Bentley et al 1954) (3) obstructive ma (perhaps as an emergency procedure) and bly stridor The advisability of bronchoscopy esence of stridor is debatable because cases have been seen where the added œdema following the bronchoscopy has been sufficient to turn a partial obstruction into a severe and dangerous one

In segmental lesions associated with primary tuberculosis bronchoscopy may well come to be used more as a diagnostic than a therapeutic weapon With the increasing use of B C G bronchoscopies may become more often necessary to establish the nature and cause of a radiological lesion in a vaccinated child The decisions regarding therapy may thus be made easier though attempts to obtain either pus or granulation tissue will it seems, succeed in only half the cases

The findings in 44 children subjected to bronchoscopy are presented in table V These children all had a primary complex with some collapse or consolidation and in 12 children bronchoscopy was repeated more than once (on four occasions in 1 child) in an attempt to clear an obstructed airway 11 of the children were aged less than 2 years and several less than 1 year yet *they presented no great technical difficulty* Various combinations of pulmonary collapse were discovered usually only one lobe was affected in particular the right upper lobe Collapse of the right middle and lower lobes was the most usual combination seen Endoscopy revealed tuberculous granulations from rupture of a gland through a bronchus in about half the cases (20 out of 44) Such granulations were always removed at operation but subsequent bronchoscopy a few months later often showed that granulations had formed again Other endoscopic findings of primary importance were bronchial narrowing from external pressure of glands (4 cases) ulceration (1 case) pus exuding from a bronchus (2 cases) and a scarred stenotic bronchus (2 cases) No abnormality was detected in 15 cases the obstruction causing the collapse being apparently beyond endosco

Including tuberculous mastoiditis and bone tuberculosis pic view, or else these may have been examples of periglandular "flare"

No particular age group derived greater benefit from bronchoscopy than any other, so the group is taken as a whole Immediate improvement was apparent in only 11, in whom removal of granulations allowed rapid re-expansion of the collapsed lobe (9 cases) or stridor to diminish considerably (2 cases) In the other 33 cases endoscopy produced no permanent change in the local condition, and re expansion of the lung took its time The deduction is that bronchoscopy can be undertaken in a child with a primary complex and pulmonary collapse in the hope of clearing the affected bronchus from caseous infective material and improving the airway Except for occasional immediate postoperative œdema with distress the procedure was harmless It must be admitted, however, that on rare occasions the postoperative condition gives some cause for uneasiness In only 1 case did further collapse occur after endoscopy

### Treatment

The general plan included hospital treatment during the very active stage and, as soon as possible, transfer to the country branch of Great Ormond Street, other convalescent institutions, or home, according to the progress and domestic circumstances of the patient When circumstances permitted, the children were treated entirely as outpatients (Hall 1951) Sanatoria specifically designated for tuberculosis were used only in exceptional cases, usually in children with parenchymatous lung lesions and cavitation Nearly all were subsequently followed in the tuberculosis clinic at Great Ormond Street or medical outpatient department at University College Hospital

Streptomycin, *p* aminosalicylic acid, and, more recently, isoniazid have been used in selected cases only Almost all (49 out of 55) the children with serious forms of tuberculosis who were admitted to hospital and subsequently died were treated with one or other or a combination of these drugs

Analysis of 477 of those who survived (table VI) showed that 19% were thus treated, those with miliary tuberculosis and tuberculous meningitis invariably and those with local dissemination almost always In dealing with a primary complex, with or without collapse and consolidation, specific therapy was given only in 6%, mostly for those with questionable spread to the surrounding parenchyma and with other complications, such as bone tuberculosis and mastoiditis irrespective of the age of the child Only 15 of the 126 children with this lesion and aged less than 3 years were given antibiotic therapy, and 11 of these were aged less than 1 year Limiting the treatment in this way runs rather counter to the ideas of many present day pædiatricians (e g, Todd 1952, Wallgren 1950), and particularly the French (e g, Debré 1951, Cathala et al 1949) who advise giving specific antibiotics to all children aged less than 1 or even 2 years with a primary complex Although the tendency now is to give all infants antibiotic treatment, the previous policy, which is adopted also by Dufourt et al (1950) and Miller (1952), seems fairly well justified when the prognosis is studied Critics might argue that more cases of miliary tuberculosis and meningitis might have been avoided if streptomycin had been used as a routine, especially in the younger children Some workers—e g, de Beule (1952) and Lorber (1950)—make the point that there is no certainty that such treatment will prevent these complications, which may even arise during therapy (Sacrez and Burghard 1951) and have done so in a very few cases in the present series The course the lesion took was usually most satisfactory, re aeration of the lung proceeded steadily, and healing took place with calcification Although the use of antibiotics in [illegible] ng lesions is undisputed, there is no evidence in the present series that they have any caseating adenitis or an associated pulmonary or that they will hasten recovery This cond accordance with the findings of Russell and (1950) and Lorber (1950)

### Lobectomy

There is little doubt that, with the passage thoracic surgery will play a more extensive treatment of tuberculosis in children The for surgery, the best stage of the disease at apply it, and the relative merits of hilar segmental or lobar resection are all subjects of Excellent results have followed lobectomy in 7 present series The children were aged 1–10 tion and 6 of the 7 had previously been bronch without benefit Only 2 children received and *p* aminosalicylic acid to cover the operation this is now standard practice They all did were discharged from hospital from ten to days after operation It is considered the operation is not indicated, and these cases for surgery because the child's general con poor and there was no evidence of healing of lesion over some years The 1 exception was aged 7 months who was not progressing after five months' observation but did very right mid and lower lobectomy at the age The endoscopy findings included granulations, ulceration, and scarring, and the lobectomy revealed collapse, bronchiectasis, caseation, cation

### Prognosis

Of the 215 surviving children who have been up from two to five years only 1 child died after the onset of the illness The outlook who have survived 2 years is good and a fair of immediate prognosis can therefore be made follow-up of this duration Most of the chil in fact, been under supervision far longer shows the clinical and radiological state when was discharged or when last seen in 1953

Of the 215 children 152 were well clinically logically, 47 were in good health but had radiological shadows (the lobectomy cases are in one or other of these groups) Only 4 were and were radiologically abnormal In ad children were under observation for non-tu conditions or because of residual complicati tuberculous meningitis Experience has resolution of the segmental lesion takes about whatever the cause, though the radiological take rather longer to clear in the younger chil

TABLE VII—PROGNOSIS IN 215 SURVIVORS

| Length of follow up (yr) | Clinically and radiological well | | | Clinically well with persistent radiological lesion | | | Ill with radiological lesion | | |
|---|---|---|---|---|---|---|---|---|---|
| | Age at onset (yr) | | | | | | | | |
| | 0–2 11/12 | 3–5 11/12 | 6–12 | 0–2 11/12 | 3–5 11/12 | 6–12 | 0–2 11/12 | 3–5 11/12 | 6 |
| 2 | 12 | 11 | 22 | 5 | 5 | 5 | (1) | | (1) |
| 3 | 13 | 17 | 14 | 4 | 5 | 2 | 2 | | |
| 4 | 11 | 14 | 8 | 5 | 4 | 3 | 1 | (1) | (1 |
| 5 + | 11 | 12 | 7 | 6 | 1 | 2 | (1) | (°) | 1 |
| Total | 152 | | | 47 | | | 4 + ([illegible]) | | |

The numbers in parentheses indicate the age (yr) lobectomy was done Since these children are now they have been included elsewhere in the table re exclude the fatal cases considered below, the liate prognosis (2–5 years) in this series is universally Even in the 13 survivors who had pleural effusion itlook seems good only 1 showing symptomless ogical abnormality within this limited period Of survivors who had local dissemination 7 did well the 12 survivors who had miliary tuberculosis all vivors who had tuberculous meningitis and all 6 iad both did well Of the 30 survivors without ications only 3 had symptomless radiological s Many of the children were left with areas of ation either in the primary focus or in the hilar or scattered in the lung fields Increasing density calcification was observed as the years passed and sumed to be good evidence of healing Later in children the area involved diminished and some calcium appeared to be absorbed

## Deaths

exact estimation of mortality in a condition with a natural history as tuberculosis is difficult The ng figures are of value only as an estimate of the five year death rate and the longer follow up will nuch greater interest It is realised also that there mavoidable selection of cases and that the over all rate is higher than it would be in entirely unselected of primary tuberculosis. The fact that some of the were *treated in the early days of streptomycin* y also has some bearing on the figures They vell be of interest however to those who work in als with a similar intake of patients to that at ospital for Sick Children and University College al.

ong the 578 patients who had active primary nary tuberculosis 58 (9 5%) died, and the lowest rate of the two hospitals was 8 7% The main found *post mortem* are given in table VIII table includes 3 cases of non pulmonary primary ulosis which were added for interest )

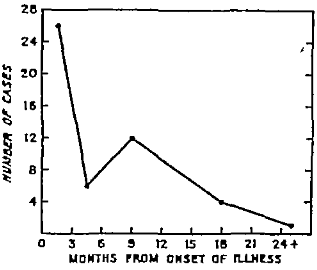
one might expect the commonest lesion was ulous meningitis with or without miliary tubercu nd this was most often observed in the younger n Tuberculous bronchopneumonia and extensive ing lesions accounted for most of the remaining For the purposes of comparison the lesions found pulmonary tuberculosis have been included and clusion of these and of those cases in which mary site was unknown does not significantly the mortality rate which was 70 out of 665 )

0 of the 55 deaths the duration of the tuberculosis be assessed accurately and the findings are shown accompanying figure Over half (26) died during st three months and a further 18 within the first There were only 5 deaths after that and only 1 lied after two years had elapsed This indicates as regards the immediate mortality a two year up is probably adequate in most cases disregarding later deaths from reinfection or reactivation tuberculosis

VIII—MAIN LESIONS FOUND POST MORTEM IN 58 CASES

| Lesion | Age at onset (yr ) | | |
|---|---|---|---|
| | 0–2 | 3–5 | 6–12 |
| ulous meningitis | 9 | 5 | 0 |
| ulous meningitis and miliary culosis | 15 | 10 | 4 |
| tuberculosis | 4 | 0 | 1 |
| ital lesions | 8 | 3 | 1 |
| dissemination and broncho monia | 7 | 1 | 0 |
| lmonary tuberculosis with or ut miliary tuberculosis and ngitis | 5 | 2 | 2 |

All except 8 cases had antibiotic treatment



Time of death in 49 cases

Table II shows the relative frequency of death from tuberculous meningitis and miliary tuberculosis alone and in combination. This includes cases with non pulmonary primary foci giving a total of 57 It shows at a glance that the presence of miliary tuberculosis in cases of tuberculous meningitis weighs *heavily against the chances of survival* In the younger age-groups 73% and 79% of children with the combined lesion died whereas only 58% and 32% of those with meningitis alone died Even in the children aged 6–12 years this striking difference is evident Miliary tuberculosis by itself however seems to be less fatal than meningitis but once again the younger the patient the worse is the prognosis. These conditions were fatal in 60% of the 55 children aged less than 3 years and in 35% of the 20 children aged 6–12 years.

With advances in antibiotic treatment the mortality rate should diminish With more immediate examination of contacts and early diagnosis it is hoped that these figures will be greatly reduced There is in fact, some evidence of improvement already

## Conclusions and Summary

The complications source of infection and bacteriology in cases of primary tuberculous complex of the lung have been studied The part played in their treatment by streptomycin and other specific antibiotics broncho scopy and lobectomy has been reviewed and the prognosis and mortality have been assessed

This study confirms once again the relatively good short term prognosis of the pulmonary primary complex in childhood The mortality rate of less than 10% in this rather selected series of cases compares favourably with the results of other units and would, of course, be reduced if the ' non active ' cases were included It might be argued that the number of cases developing serious complications, and therefore the mortality rate would have been lower if streptomycin and other specific antibiotics had been used more often

It seems unlikely that the unusually high incidence of segmental lesions observed in this series is due to this factor it arises through unavoidable selection of the more serious cases the classification used and the individual variation in terminology and interpretation of the radiological segmental lesion A follow up for two to five years has shown that most of these lesions resolve within two years.

The extremely low incidence (4 2%) of proved bronchiectasis following such lesions is explained by the fact that the resulting bronchial dilatation is usually symptomless and does not impair general health Usually bronchography was done only in cases with persistent ill health and abnormal clinical findings therefore proof of the presence of these symptomless lesions (which seem to be of little importance) is wanting

The presence of miliary dissemination in cases of tuberculous meningitis weighs heavily against the chances of survival and these two complications of the primary complex remain the principle dangers. This review includes the early streptomycin era, it is therefore hoped that future series treated with this and the newer antibiotics, alone or in combination, will have a lower mortality. The value of streptomycin and *p*-aminosalicylic acid in these cases has been obvious, yet in this survey 60% of children aged less than 3 years, of whom practically all received this treatment, died from these conditions. A plea is made for early diagnosis and institution of treatment, and examination of all contacts, particularly of children aged less than 3 years.

Although bronchoscopy has been of some value in diagnosis, and with the increasing use of B C G will probably become more so, its use in treatment is very limited. Greatest benefit has been derived in cases with stridor and obstructive emphysema, and most workers agree that these findings justify bronchoscopy. Opinions vary about the other indications for bronchoscopy, but these probably should include massive persistent collapse, particularly of the lower lobes.

Lobectomy is undoubtedly well borne by children, and one is impressed by the short time it takes them to become fully active after the operation. Although some workers advocate early surgical intervention, it is the opinion of most that lobectomy should be reserved for cases which have not responded to a reasonable period of adequate medical treatment.

I am greatly indebted to Dr B E Schlesinger for the clinical details of his cases from University College Hospital and the Hospital for Sick Children, to Dr Marcia Hall for the clinical records of the cases attending the tuberculosis clinic, and to both for their invaluable help and kindly encouragement in the production of this paper. I thank the physicians at the Hospital for Sick Children for granting access to the records of cases in their charge, Mr James Crooks, Mr H S Sharp, and Mr D J Waterston for their bronchoscopy reports, Prof R S Pilcher and Mr Waterston for the lobectomies, Dr Martin Bodian and staff for necropsy and biopsy reports, Dr I A B Cathie and staff for the bacteriological findings, Dr L G Blair and staff for radiological reports and advice, all the housemen and registrars whose notes made this report possible, and the chest physicians of various clinics for forwarding follow up reports.

# INITIAL CONTROL OF HYPER WITH PENTOLINIUM TARTRAT

DESMOND W ASHBY
M.D Lond, M R C P
PHYSICIAN TO THE GATESHEAD GROUP OF HOSPITAL
COUNTY DURHAM

JOHN O'NEILL
M B Durh, D.P.M.
REGISTRAR, BENSHAM GENERAL HOSPITAL, GATE

MARY C MACLEAN
M.B Durh, D P.H, D P M
REGISTRAR, QUEEN ELIZABETH HOSPITAL, GAT

ALTHOUGH a completely satisfactory treat essential hypertension has yet to be devised, re have produced a surfeit of hypotensive drugs, many are no better than a placebo, but some— hexamethonium and pentolinium tartrate—have their worth sufficiently to supplant sympathec a treatment of choice

In the Gateshead group of hospitals methon have been used from the autumn of 1950, and to their effect more completely a clinic for hyp started in the summer of 1951. From Octob pentolinium tartrate ('Ansolysen') was used subsequently most of the new patients with hyp were treated with this drug in preference to At present the patients who were receiving methonium with a retarding agent by daily sub injection are being given pentolinium tartrate by

The results of this policy will take some years to we report here merely the method used for st patients on pentolinium tartrate in hospital.

## Type of Patient Selected

Up to now 72 hypertensives have been ad hospital for treatment with pentolinium tartrat method of selection was similar to that of M (1952). We recognise the following groups:

(1) Labile hypertensives, with diastolic pressure be mm Hg but no complications, who require only reassurance, and reduction of obesity.

(2) Patients with persistent hypertension (diastolic 120 mm Hg or higher) and established complicatio

(3) Patients with malignant and premalignant hy

Most of the patients treated with pentolinium t were in groups 2 and 3. They had persistent diastolic blood pressure or persistent symptoms headache, breathlessness, dizziness, and failur Nevertheless, if severe symptoms were present, with diastolic pressure as low as 100 mm H treated.

## Symptoms and Signs

The following symptoms were present in the 7 at the time of selection for treatment:

Headache
Feeling of fullness in head
Dyspnœa
Vertigo
Angina pectoris
Fainting
Palpitations
Paræsthesiæ of extremities
Noises in head
Dependent œdema
Epistaxes
Failing memory
Loss of concentration
Failing sight due to hypertensive retinopathy

The age and pathological distributions were as

| *Age* (*yr*) | Male |
|---|---|
| 20–30 | 1 |
| 31–40 | 1 |
| 41–50 | 5 |
| 51–60 | 3 |
| 61–70 | 4 |
| 71–80 | 8 |

| ogical distribution | | |
|---|---|---|
| ign essential | 11 | 41 |
| gnant | 1 | 5 |
| al | 0 | 1 |
| locrine | 0 | 0 |
| rosclerotic | 1 | 8 |
| ertension following toxaemia of pregnancy | | 1 |

re were 59 females and 13 males Most of the its were in the 6th decade

### ocardiographic Changes

the 72 patients 47 showed electrocardiographic es amounting usually to those associated with left icular preponderance and axis-deviation 28 of these lso inverted T waves and S–T segment abnormalities t ventricular strain. 1 patient with associated ysema and cor pulmonale had right axis deviation

### graphic Changes

patients showed appreciable enlargement of the entricle and massive cardiac enlargement was it in 2.

### l Changes

70 patients whose fundi were visible fundal changes present as follows grade 4 in 5 grade 3 in 8 rade 2 in 35 Grade 1 changes in the vessels were t in 9, and there were none demonstrable in 13

## Contra indications

se patients were not admitted until 1000 calories d weight reduction had been given a thorough trial ue A history of angina pectoris, coronary throm or cerebral thrombosis was not regarded as contra ting treatment with pentolinium tartrate and mild ion did not prevent its use Senile dements were ed A raised systolic blood pressure with arterio us was not treated unless accompanied by per ly raised diastolic pressure

do not intend to discuss the effects of pentolinium te on renal blood flow Tests of renal function f limited character A raised blood urea level or paired urea clearance previous nephrectomy or s kidney disorder was a signal for circumspection rising blood urea level led to discontinuation of ent Patients with malignant fundal changes reated despite a rising blood urea level. The single assified as renal hypertension was one of only mild ephrosis, with normal renal function and this t has so far done well However since this series mpleted a rapidly rising blood urea level has been ed during treatment of 1 patient who had had s nephrectomy for hydronephrosis

ents with prostatic symptoms intestinal distension oma should not be treated

## Procedure in Hospital

patients were re examined on arrival and uro tests urea-clearance tests, intravenous pyelo- chest radiography and electrocardiography were Piperoxane or phentolamine tests were given to d patients Of 72 patients only 1 was found to nilateral renal disease on routine pyelography and ubtful whether this procedure is necessary when ne is chemically and microscopically normal The l pulses of all patients admitted were examined the present 72 and the 185 followed in the clinic pertensives no case of coarctation of the aorta o our notice

### Observations

often stated (e g Ronnov-Jessen 1954) that the should have a preliminary eight to fourteen days ital to allow the blood pressure to reach a resting Though we admit the desirability of a control we are doubtful whether it is economically to give such periods of up to a fortnight to s who may occupy a quarter of the beds in the hospital wards In place of this one can rely on preliminary outpatient observations coupled with a known history of hypertension and a relatively short period of up patient observation in hospital followed by a control day of two hourly blood pressure readings It is not important to know whether the patient s blood pressure will come down to near normal with rest in bed in hospital nor is it essential to give from three to five days rest in hospital before observations are made on blood pressure response to hypotensive drugs The problem is not the patient in hospital but the patient in home office or workshop Comparative freedom from the constant irritations and worries of domestic and working life make hospital surroundings artificial and lessen the value of blood pressure readings taken there Ideally blood pressure observations should be made in kitchens offices workshops, and factories The alternative in a medical ward is the encouragement of activity Patients were therefore kept up between 8 A.M and 8 P M and required to walk twice the length of the ward before recordings were taken

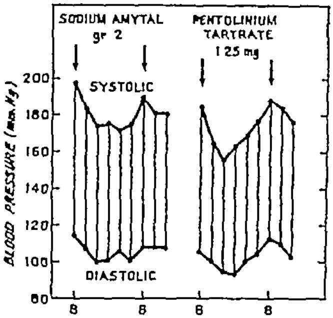

Fig 1—Comparison of effects of sodium amytal gr 2 and subcutaneous pentolinium tartrate 1 25 mg given at 8 a.m. and 8 p.m (averages of blood pressures of 12 patients)

Morning blood pressures may be rendered abnormally low by the use of barbiturate sedatives which were therefore not given during the period of hospital assessment The effect of Sodium amytal' on the blood pressures of 12 patients is compared with that of pentolinium tartrate in fig 1

### Day before Trial Dose

Control observations were made on the blood pressure every two hours from 8 A.M until midnight In the case of known hypertensives of some years standing this

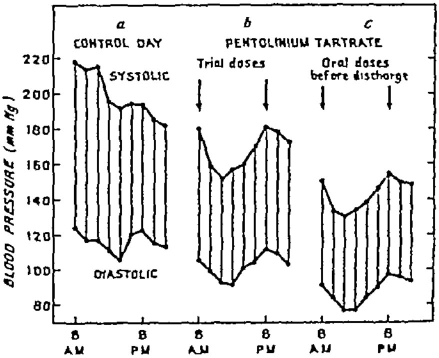

Fig 2—Average blood-pressure readings of 12 hypertensives two-hourly from 8 a.m. to midnight. Average time between b and c is ten days.

could be done on the first day Admittedly the morning blood pressure tended to fall spontaneously on subsequent days but the effect of pentolinium tartrate could be assessed by the shape of the two hourly curve without reference to the day to day fall

Fig 2*a* shows the average results of two hourly blood-pressure controls in 12 hypertensives who were up between 8 A M and 8 P M and in bed subsequently The day time blood pressures were observed after brisk walks along the ward It will be seen that the blood-pressure had dropped by 2 P M and reached a day-time minimum at 4 P M This fall took place in 9 of the 12 patients from whom the average blood pressure curves are constructed in the figure After 4 P M the blood-pressure rose again, reaching a peak when the patients received their visitors between 7 and 7 45 P M, and fell after their return to bed at 8 P M Lights were extinguished at 10 P M

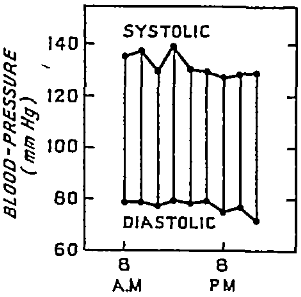

**Fig 3—Average blood-pressure readings of 12 normotensives two-hourly between 8 a.m and midnight. Compare fig 2*a* and note absence of fall of diastolic blood pressure at 4 p m and smaller fall between 10 p m and midnight.**

The importance of this control is manifold It establishes that the hypertension is persistent throughout the day, and it serves as a base from which the effects of hypotensive agents can be estimated Were this control to be omitted, the 4 P M fall might be attributed incorrectly to the effect of pentolinium tartrate The diurnal variations of blood-pressure may serve as a guide to variations in the dosage of the hypotensive drug

Fig 3 shows the corresponding two hourly control blood-pressures taken in normotensives The fall at 2 P M is no longer seen, the fall at 4 P M is very much less, and the blood-pressure varies much less than in hypertensives (fig 2*a*)

## *Day of Trial Dose*

On the following day a subcutaneous trial dose of pentolinium tartrate was given The makers recommend a trial dose of 2 5 mg but this occasionally alarming falls in blood pressure, therefore all the patients were given a trial dose of 1 25 mg Ev comparatively small dose led to diastolic blood of 50 mm Hg and associated faintness requir venous methylamphetamine in 3 patients, 1 of severely shocked, sweating, and pale

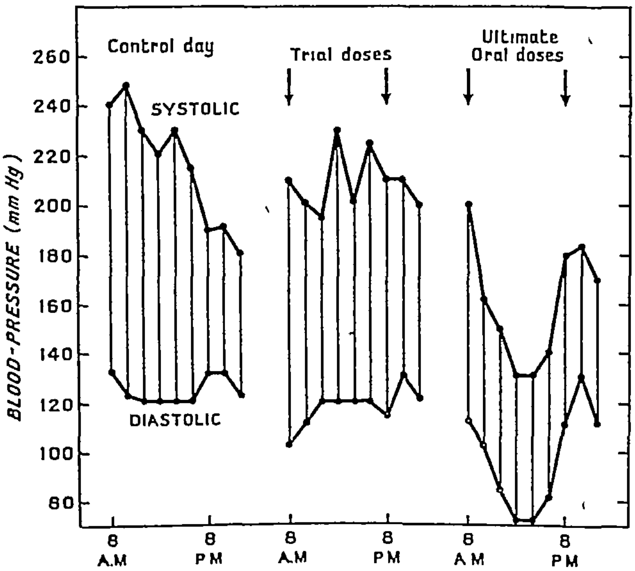

**Fig 4—Two-hourly blood-pressure readings in a patient who gave no response to trial doses of pentolinium tartrate 1 25 mg subcutaneously Note subsequent response to twelve-hourly dosage ( curve indicates that eight hourly dosage would be better)**

This trial dose was given solely to detect reactions In 15 patients the blood pressure did appreciably after the trial dose, but such response was not regarded as contra indicat treatment (fig 4) In 12 of these 15 patients not respond to their trial dose the blood successfully reduced in hospital

2 patients had unexpected falls in blood pre in the treatment 1 was a moderate fall on the day, the other was a more dramatic fall on t teenth day (fig 5)

Fig 2*b* shows the average blood pressure of h tensives given a trial dose of pentolinium tartra 8 A M 1 25 mg was given The maximal effect noon, and some was still present at 2 P M, but it was wearing off by 4 P M The blood-pressure sometimes regained the previous levels between 6 P.M and 8 P M if no further dose was given

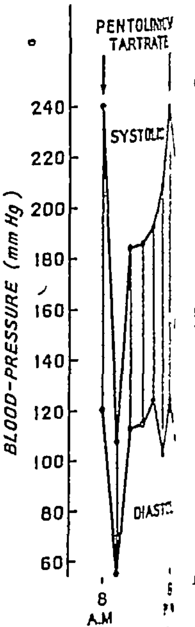

**Fig 5—Excessive fall pressure on nineteenth treatment with tartrate.**

## *Subsequent Days*

The trial dose was repeated on the evening of the first day, on the second day the dose was increased to 2 5 mg, and thereafter daily increments were made until the diastolic blood pressure reached 80 mm Hg The dose can be given either twelve hourly at 8 A M and 8 P M, eight-hourly at 7 A M, 3 P M, and 11 P M, or seven hourly at 7 A M, 2 P M, and 9 P M The shape of the curve produced by the subcutaneous trial dose should help one to select the proper interval between doses, but the individual convenience of the patient must be considered

We usually reduced the diastolic pressure to Hg by subcutaneous injections before changing tablets, 40 mg of oral pentolinium tartrate being lent to 2 5 mg of subcutaneous pentolinium This policy was dictated by the considerati patients might require such high dosage of pen tartrate as to render oral preparations unsafe, tating a reversion to the subcutaneous route happened in only 1 case of malignant hyperten oral preparation is now being successfully earlier at one hospital, where sometimes only the dose is given subcutaneously Pentolinium tartr usually much better tolerated by mouth than cutaneous injection, and, when excessive giddiness or hypotension followed subcutaneous a change to the oral route was usually all th necessary

With oral pentolinium tartrate the dose was by 20 mg (half a tablet) each day until the blood-pressure fell to 80 mm Hg and remain for at least two readings on both of two success

TABLE I—IMPROVEMENT

| Symptom | Present on admission (no of cases) | Still present but improved (no of cases) | Complete relief (no of cases) |

g the course of hospital stabilisation 1 patient n cerebral hæmorrhage

e 26 patients whose diastolic pressure was not to 80 mm Hg most were disharged for such social as responsibility for children in the home business or a previously booked holiday In es of patients we reduced the diastolic pressures nm Hg in most of the non malignant hyper

I shows the improvement in symptoms from twelve months after discharge It will be seen melioration of the major symptoms of hyper headache breathlessness and giddiness is in three-quarters of the cases Angina sometimes l as a contra indication of treatment was helped The most striking result concerned repeated which did not recur in 11 out of 12 patients l up to twelve months Compared with other series, improvement of vision was a disappointment although in the early stages of treatment of malignant hypertension it was occasionally remarkable

LE II—SIDE EFFECTS OF PENTOLINIUM TARTRATE

| effect | No of cases | Subsequent improvement (no of cases) | Remedy |
|---|---|---|---|
|  | 0 | 0 | Treatment discontinued |
| ion | 11 (15%) | 0 | Simple laxatives cholinergic drugs |
|  | 0 | 0 | Chalk mixtures |
| outh and a | 26 (36%) | 13 | Pilocarpine nitrate gr 1/5 neostigmine 15 mg |
|  | 0 | 0 |  |
| of urine | 0 | 0 | Urecholine |
| sion due to s of accom on | 14 (19%) |  | Eserine drops in eyes, change of spectacles |
| lls of blood | 5 (7%) | 5 | Methylamphetamine |

*Side-effects*

With dosages of either 220 mg three times a day or 280 mg twice a day severe reactions such as paralytic ileus and retention of urine, were not observed Larger doses were not used, because we felt that ileus might follow their use Table II shows the side effects observed in the 72 patients treated

Most of the patients tolerated dryness of the mouth without undue complaint the remainder were helped by pilocarpine It was not usually necessary to instil eserine drops into the eyes Where paralysis of accommodation made reading difficult patients had their spectacles changed as soon as a reasonably constant dosage was reached

## Aftercare

Within three weeks from their discharge from hospital all the patients were seen at the clinic for hypertensives when their progress was reviewed and dosage changed if necessary

Very few patients maintained the lower levels of blood pressure after discharge from hospital therefore the dosage of pentolinium tartrate almost invariably had to be increased Symptomatic relief, however, persisted

Some of these patients have now been followed for twelve months During this time 2 of them have died of cerebral hæmorrhage (1 had ceased to attend the clinic) and 1 who had malignant hypertension has died of pulmonary embolism complicating left and right ventricular failure

## Conclusions and Summary

After three years experience of the treatment of hypertension in hospital and in a clinic for hypertensives a method of initial stabilisation of patients on pentolinium tartrate has been evolved

The method requires that patients shall be up during the greater part of the hospital day and be exercised before blood pressure estimations which are taken sitting erect two hourly

The initiation in general practice of hypotensive treatment with pentolinium tartrate is inadvisable because of the liability to occasional severe reactions which need prompt counter measures

Pentolinium tartrate is rapidly superseding hexamethonium retard as the hypotensive agent of choice

In essential hypertension and in a few cases of malignant hypertension it is possible to reduce a patient's diastolic blood pressure from almost any level to 80 mm Hg for three or four hours out of twelve on several successive days before the patient leaves hospital

It has not usually been possible to maintain the blood pressure at this level after the patient has left hospital Nevertheless blood pressure levels achieved with hexamethonium and other drugs can be equalled and symptomatic relief is the rule

Preliminary two hourly blood pressure readings are important in deciding the subsequent treatment

After the midday meal there is in ambulant patients a natural drop in the blood pressure which might be mistaken for a therapeutic effect if these control blood pressure readings were not taken

The trial dose of pentolinium tartrate should be only half that at present advised by the makers

Failure to obtain a response to a trial dose should not deter one from treating with pentolinium tartrate because a bigger dose usually produces a satisfactory response

Our grateful thanks are due to Dr C N Armstrong for permission to include cases admitted into his care at the

Queen Elizabeth Hospital, Gateshead, and to Dr H A Dewar, who first encouraged the use of pentolinium tartrate in place of hexamethonium in the hospital group and has advised us constantly since

# "EPIDEMIC VERTIGO" WITH OCULOMOTOR COMPLICATION

A W D LEISHMAN
M A , D M Oxfd F.R C.P
CONSULTANT PHYSICIAN, UNITED SHEFFIELD HOSPITALS AND DONCASTER GATE AND MOORGATE HOSPITALS, ROTHERHAM

A GENERAL practitioner requiring assistance with a patient who has suddenly developed vertigo is likely to find the choice of consultant a little embarrassing Shall he burn his boats and summon a neurologist or an otorhinologist or more cautiously turn to a general physician as a neutral referee ? Ultimately each of these specialists sees his fair share of such cases, and from his individual experience each would probably be able to recollect an occasional example of the mysterious malady usually referred to in this country as "acute labyrinthitis"

Perhaps on account of its sporadic occurrence and benign character, the condition does not seem to have attracted much attention until the appearance of an annotation in *The Lancet* (1952) This suggested that there might recently have been a small epidemic of this disease and cited the experience of a Hampstead doctor who had had 6 cases in his practice during January, 1952 In the subsequent brief correspondence only two general practitioners (Currie 1952 and Fry 1952) claimed to have had a similar experience in the immediately preceding months , but later Burrowes (1952) described elsewhere 6 cases of this type seen in a general practice during the same period. Several other writers indicated that they were familiar with the condition and in particular Worster-Drought (1952) contributed an authoritative account based on records of almost 50 cases seen in neurological practice over a period of seven years The features which he considered characteristic were vertigo of sudden onset with vomiting and nystagmus, though this last feature was by no means always present Coördination appeared never to be affected, and there was rarely significant deafness though some patients described transient tinnitus Recovery was the rule, though this might take from six weeks to twelve months and in the early stages relapses were common Worster-Drought emphasised that "acute labyrinthitis" (a designation which he accepted) could be diagnosed only after other causes of vertigo had been excluded, and that in this connection the absence of persistent deafness and tinnitus was strong evidence against Ménière's syndrome

More recently Dalsgaard-Nielsen (1953) has summarised a study of 21 cases of "epidemic vertigo" admitted to hospital in Copenhagen within the past few years These cases he considered were representatives of an epidemic which had been prevailing in Denmark generally The chief interest of this paper lies in the additional features which were occasionally observed, for in its essentials the clinical picture seems to have been identical with that seen previously in this country 2 of the patients, for example had diplopia, and one or two more had unequal pupils Hiccup was a complication on 2 occasions, and 6 of the 13 cases studied by electro encephalography were said to show dysrhythmia Although the cerebrospinal fluid (C S F ) was invariably found to be normal Dalsgaard-Nielsen concluded that there was every justification for regarding this condition as encephalitis

My first encounter with this rather alarming found me singularly unprepared Indeed had it my good fortune to see in rapid succession of almost identical character, I would remained unenlightened Some of the cases in the outbreak, however, presented features which appear to have been described in this country

## Case-reports

**Case 1** —A fitter, aged 54, seen in consultation 1954, had been perfectly well until ten days previously on return from a football match he was suddenly intense vertigo At the same time he began to vomit ing persisted for three days, and he remained in any change of posture caused renewed vertigo after the onset, following a bout of vomiting diplopia which persisted and did not vary with ment At the same time he was aware of transient tinnitus in the right ear, but he had not noticed any He had had no headache or other symptoms, and afebrile He had had no previous illnesses of

*On examination* his general condition was good, comfortable while lying supine , change of posture vertigo, though this was less severe than previously cardiovascular system was normal , blood pressure Hg with no palpable thickening of arteries abdomen were normal There was no neck optic discs were clear , there were no retinal changes reactions were normal , eye movements appeared there was no nystagmus, but diplopia was present the range of eye movement , there was no cranial nerves were otherwise normal There was no tremor or other evidence of incoördination of arms tendon reflexes were brisk and equal , power and of all limbs were normal , the abdominal present , the plantar responses were flexor Urine

The diagnosis at this time appeared uncertain thought that a small brain stem thrombosis might these developments After a further week, since little improvement in his condition, he was Doncaster Gate Hospital, Rotherham, for lumbar and further study

*Investigations* —The C S F , which was under normal and was clear, contained 14 red blood-cells and cytes per c mm and protein 70 mg , sugar 82 mg 738 mg per 100 ml , the Lange gold curve was and the Wassermann reaction and Kahn test were The erythrocyte sedimentation rate was 9 mm in the (Westergren) , blood count normal. Radiographs and chest were normal. An ear, nose, and throat could find no aural abnormality, but an reported that the diplopia was due to paresis of superior rectus

*Treatment and Progress* —The patient was treated low salt diet, and continued mild sedation. improved and left hospital after a six week stay weeks after the onset he was still troubled by slight postural dizziness

**Case 2** —A girl student, aged 19, admitted to Infirmary, Sheffield, on Oct 5, 1954, had been until two days previously when unusually for late, failing to hear her own alarm clock and two She was aroused with some difficulty and noticed On getting out of bed she tended to stagger to the there was no true vertigo Twenty four hours developed occipital headache and vomited remained drowsy throughout the day At this doctor could find no neurological signs When hospital the following morning she was already she was bright and cheerful and free from headache and diplopia, though she described at first some focusing objects

*Examination* —On admission her temperature and pulse rate 100, but within twenty four hours normal Routine clinical examination was negative pressure 120/45 mm. Hg Urine normal There rigidity, and Kernig's sign was negative , pupil normal, and there was no nystagmus , to ordinary movements were full although occasional e was observed (full ophthalmic examination a day ater revealed no ocular paresis); optic discs clear ess No incoördination or paresis of limbs tendon minal reflexes normal and plantar responses flexor; unimpaired. On lumbar puncture the C.S.F. pressure ult to record but appeared lower than normal The s clear and contained no excess of cells; the protein was 30 mg and sugar 65 mg per 100 ml. the Lange ve was normal. White blood-cells numbered 5000 with normal differential count.

ss was uneventful and the patient returned to ing-college after a week's stay in hospital by which was free of symptoms She has remained well since gnosis again was in doubt: mild encephalitis was to be a possibility but disseminated sclerosis could gether be excluded.

3.—A poultry farmer aged 27 admitted to the firmary Sheffield on Oct 20 1954 had been very until six days before admission when he had been seized with vertigo while going to bed The vertigo he remained in bed and the following night was vomiting During the next few days he improved and did not again vomit but on the day before n the vertigo was more pronounced and his doctor lely dilated inactive pupils. There was no complaint che or diplopia, but there was occasional tinnitus ght ear

*ation.*—On admission his general condition was good vas afebrile Routine clinical examination was nega lood pressure 132/64 mm. Hg Urine normal There neck rigidity and Kernig's sign was negative pupils l size and active optic discs clear eye movements but pronounced rotary nystagmus was present ed by extension of the head and on looking to the ere was no deafness or evidence of local ear disease tion of the central nervous system otherwise revealed rmality power and coördination of limbs was , abdominal and tendon reflexes were normal and ar responses were flexor and sensation was unim On lumbar puncture the C.S.F., which was clear and ormal pressure contained 1 cell per c.mm and 0 mg and sugar 55 mg per 100 ml Lange gold as normal White blood-cells numbered 8000 per th a normal differential count

*s.*—There was at first little improvement in the nd once sudden vomiting without warning followed of retro-orbital headache Anti histamine drugs to bring some relief and after a week nystagmus ed and recovery was well established and after in hospital the patient returned home When seen later he reported himself fully recovered apart from y to slight postural dizziness

—A shop assistant aged 25 seen in consultation 22 1954 had been well until three days previously he evening she had occipital headache and felt slightly hile at work the next morning she developed without cute vertigo and felt sick but did not vomit Return with difficulty she went to bed where the vertigo on any change of posture but she did not notice The following morning she complained of diplopia some left-sided retro-orbital headache but the as considerably improved

*mination* her general condition was good and she greatly distressed There was no fever Routine amination was negative; blood pressure 140/85 mm urine was normal There was no neck rigidity and sign was negative; both pupils were widely dilated ed only very slightly to light and on accommoda ere was evident paresis of the left internal rectus d gross rotary nystagmus on lateral eye movement tinct to the right; optic discs and retinæ were there was no deafness or other abnormality of erves Power and coördination of limbs were l; tendon and abdominal reflexes were normal plantar responses were flexor; and sensation was al.

*tions.*—The patient was admitted the next day aster Gate Hospital Rotherham, where lumbar yielded clear C.S.F. under normal pressure this no excess of cells the protein content was 30 mg ml. and other constituents were normal White s numbered 6200 per c.mm. with normal differential count An ophthalmologist confirmed the paresis of the left internal rectus and in addition drew attention to the presence of slight left-sided ptosis and paresis of the left inferior oblique muscle

*Progress.*—The patient recovered rapidly and within a further twenty four hours was free from vertigo nausea, and diplopia. At the end of a week she was discharged from hospital free of symptoms and with complete recovery of eye movements When seen a fortnight later she had no complaints.

**Case 5.**—A married woman aged 53 seen in consultation on Oct 23 1954 had been in excellent health until two days previously when while sitting in a friend's house she was suddenly attacked by acute vertigo accompanied by vomiting She was helped home and had remained in bed since lying very still because any change of position brought renewed vertigo She had not vomited again but noticed tinnitus in the left ear There was no diplopia but photophobia was quite pronounced Headache had not been a feature

*On examination* her general condition was good and routine examination was negative she was afebrile blood pressure 103/70 mm. Hg The urine was normal There was no neck rigidity and Kernig's sign was negative pupils were normal and optic discs clear eye movements were full but coarse nystagmus occurred on looking to the right. There was no deafness and cranial nerves otherwise were normal There was no loss of limb coördination and power abdominal reflexes were present and tendon reflexes were unaltered

*Investigations.*—The patient was admitted the same day to Doncaster Gate Hospital, Rotherham where lumbar puncture yielded clear C.S.F. under normal pressure containing no excess of cells and protein 55 mg per 100 ml; the Lange gold curve was negative. White blood-cells numbered 4600 per c.mm. with normal differential count

*Treatment and Progress.*—Despite treatment with a low salt diet and anti histamine drugs the subjective vertigo was slow in clearing but nystagmus persisted for only twenty four hours after admission. The patient returned home largely recovered after twelve days in hospital and when seen a fortnight later was complaining only of slight dizziness

## Discussion

The use of the term outbreak for a series of 5 cases may seem a little portentous, but there is some evidence to justify this description In the first place with clinical features so remarkably similar it can scarcely be doubted that each of these patients had the same disease and although a span of six weeks separated the appearance of the first and last cases the last 3 cases were seen virtually on successive days Lively expectations of an epidemic were not realised and as far as can be discovered there has not been a single further case All of the patients came from one locality living either in or within a few miles of Rotherham and during the same period no similar case appears to have been seen by consultant colleagues among the adjacent and much larger population of Sheffield It has been impossible to trace any connection or common source of contact among these 5 patients each of whom came from an entirely different walk of life

Fundamentally these cases conform exactly to the pattern noted previously Thus the patients were apparently all in excellent health up to the time of onset and in 3 the onset was dramatically sudden Invariably the initial symptom was vertigo or at least severe giddiness followed rapidly by vomiting of cerebral type or nausea None had ear disease or deafness, but 3 noticed transient tinnitus Nystagmus was observed in 3 cases; in 2 of these it was of rotary and labyrinthine type intensified by extension of the head but in no case was there any loss of coördination

The single feature which seems to distinguish this outbreak from any previously reported in this country is the occurrence of diplopia. Of the patients in this series 3 had diplopia and in 2 of these undoubted ocular pareses were observed. There is a strong probability that a 4th patient (case 3) also had involvement of the oculomotor nerve for dilated inactive pupil wer noticed by his doctor at one stage, and these were also observed in one of the patients (case 4) with external ocular pareses In the account of the Danish outbreak (Dalsgaard-Nielsen 1953) diplopia or pupil changes are mentioned in not more than 3 or 4 of the 21 cases reported, in comparison therefore the incidence of these complications in this small outbreak has been much higher

Obviously it should be more widely known that oculomotor control may also be disturbed in this condition, for without this information the diagnosis, at least in isolated cases, is bound to cause difficulty and probably some anxiety It follows also, in view of the wider neural involvement shown by these cases, that the description "acute labyrinthitis" is no longer acceptable On the other hand, in view particularly of the consistent failure to demonstrate any excess of cells in the C S F, some may find the concept of this disease as a "form of encephalitis" equally difficult to support At present, therefore, any description had best be non-committal, and for this reason the title "epidemic vertigo" has here been preferred

### Summary

A small outbreak of the disease usually referred to in this country as "acute labyrinthitis" is described.

This outbreak was confined strictly to one locality, but no source of common contact could be identified

An unusual feature was the high incidence of oculomotor disturbance—a complication, observed occasionally in a recent Danish epidemic, which has apparently not hitherto been reported in this country

It is suggested that until more is known of the ætiology of this disease the title "epidemic vertigo" is preferable to "acute labyrinthitis"

# THE HAIR OF THE PILONIDAL SINUS

F E WEALE
M B Lond, F R C S
LATE REGISTRAR, DEPARTMENT OF MORBID ANATOMY,
WESTMINSTER HOSPITAL, LONDON

SINCE Warren (1854) first described the pilonidal sinus a century of speculation has not finally decided its mode of origin Various developmental theories have been put forward from time to time (Hodges 1880, Wendelstadt 1885, Herrmann and Tourneux 1887, Bland-Sutton 1922, Oehlecker 1926) The embryology of the sacral region has been under more recent review (Kunitomo 1918, Kooistra 1942) The view of Patey and Scarff (1946, 1948) that the pilonidal sinus is essentially traumatic emphasises the weak foundations on which the developmentalist theories are based

In the present study the hair in the pilonidal sinuses was examined to determine its origin The premises were these

(1) If the sinus is a developmental anomaly, the hair should be growing out towards the skin surface in a more or less orderly fashion

(2) If the pilonidal sinus is the result of a mechanism such as was suggested by Patey and Scarff (1946), hairs found in the sinus should be lying at random in relation to the axis of the sinus

### Methods and Materials

Seven sacral pilonidal sinuses removed at were subjected to serial section The sections, 15 μ thick, were stained with Heidenhain's 'Azan' to demonstrate the structure of the hair cuticle

Direction of hair growth can be deduced from the direction in which the cuticular scales lie In practice, if hairs are cut obliquely and appear as oval discs, and if infection blurs the cuticular outline, difficulty may be experienced in deciding which way a hair has been growing The following criteria are then helpful

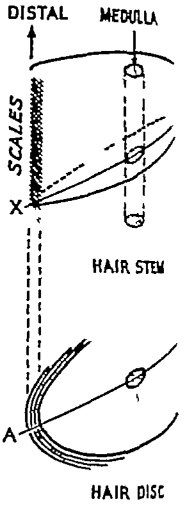

Fig 1—Oblique section (A hair stem cuts more mal end (A) than at hair segment. The more closely packed the

(1) The medulla is usually nearer the proximal extremity of the hair disc (fig 1)

(2) The basal edges of individual hair scales appear more closely packed than their distal cusps The former are smooth, the latter ragged.

(3) More dye tends to concentrate over the pro *of the hair disc*

(4) Owing to capillary attraction a dark band found just distal to the cusp of a scale, but as overlap the proximal scale is just a shade darker distal one

### Findings

The parallel course of many hairs suggest must originate in a fairly circumscribed are followed to their source (see above), apparent that they originate in the depths of Their deep ends are club shaped They in the lumen of the sinus, or they may still to the sinus wall (fig 2) In the uninfected points of attachment may show par may extend along the sinus wall

If it is accepted that the fine lanugo like hair hair (the club-like expansions make this virtual, all that should remain of the follicles is their External root sheaths may be seen soon after been extruded, the intercellular cement characteristically sloping into the lumen of away from the root base The internal root for a time, stick to the extruded hair Later remains as pale loose debris

Two kinds of epithelial linings are seen highly keratinised, and rich in rete pegs narrow, pale, and practically devoid of rete predominates in infected sinuses, and secon from islands of the thick original epithel inflammation has subsided

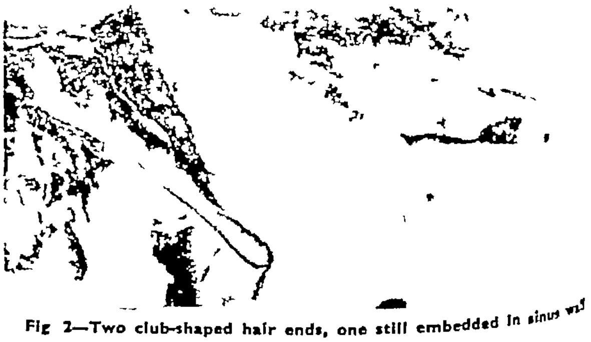

Fig 2—Two club-shaped hair ends, one still embedded in sinus wa

d inflammation become chronic masses of tion tissue are formed, encroaching on the lumen nus, burying the epithelium and finally absorbing ) With the epithelium hair particles are similarly in the granulation tissue but being unabsorb ey retain their histological identity They can e found some millimetres outside the chronic yet they betray their origin by the common n of their scales

kin overlying the sacral pilonidal sinus contains ly deep hair papillæ In a formol preserved erefore shrunk specimen they may be up to deep well in the subcutaneous fat The follicles separate from the sinus may be abnormally id carry two hairs each None of these features ionstrable in the sacral skin of normal controls is probable that they are an expression of the evelopmental anomaly which leads to the fully sinus They may be the precursors of undeveloped

### Discussion

ng developmentalists the precise mode of forma the pilonidal sinus is undecided The disparity n tail development and the cephalad movements pinal cord and skin introduces so many confusing that the segmental orientation of the sacral difficult to assess Though pilonidal sinuses are nes associated with other sacral developmental it is well to remember that such defects often n crops a causal relationship between one and is impossible to prove

findings on tracing the origin of the hair to the the pilonidal sinus provide evidence that this is elopmental defect The notorious absence of pillæ is no bar to such a view when the hair within us is recognised as shed.' Indeed the case with hair can be teased out of a sinus in the living would make any other finding surprising

Granulation tissue entering lumen of sinus and absorbing squamous lining (× 50)

### Summary

d section of pilonidal sinuses has demonstrated eir contained hair originates in their depth, and o sinuses are therefore developmental defects

r infection hair may penetrate the sinus wall and o lie outside the sinus Independent hair papillæ skin close to a sinus have been found to reach an l depth.

I wish to thank Dr A. D Morgan for his help and advice and Mr F E Wilson and Mr M Cuthbertson for their help with the histological preparations.

# CEREBROSPINAL FLUID IN CARCINOMATOSIS OF THE MENINGES

E F Murphy
M.D N U I D C H.
SENIOR REGISTRAR, SEACROFT HOSPITAL, LEEDS

Cerebrospinal fluid (C.S F) containing little sugar and much protein and many cells is often regarded as pathognomonic of tuberculous meningitis. That carcinomatosis of the meninges can produce a similar picture has only recently been recognised (McCormack et al 1953) Apart from Forster (1930) and Platt (1951) who referred to the occasional recognition of tumour cells in the C.S F and Jacobs and Richland (1951) and Strange (1952) who reported low sugar levels few workers have correlated the presence in the C.S.F of neoplastic cells much protein and little sugar with the necropsy findings The similarity to tuberculous meningitis is illustrated by the following case

A man aged 64 was admitted to Seacroft Hospital on June 20 1954 with the diagnosis of tuberculous meningitis He had had pain in his trunk and limbs for twelve weeks this had become worse gradually in the last month when he had lost much weight and had developed pain and stiffness in his neck Thirteen days before admission he had a generalised convulsion with a period of unconsciousness. In the past he had been a miner and was in receipt of a pension from the Silicosis Board

*On examination* he was pale and wasted with a very stiff neck and a positive Kernig's sign His cranial nerves were not affected, his optic fundi were normal and there were no choroidal tubercles. His right lung showed emphysema with crepitations in the upper zone

*Investigations*—Radiography on July 1 showed pneumoconiosis with parenchymal infiltration of the upper zone of the right lung

Lumbar puncture on July 1 produced C.S F containing lymphocytes 100 per c.mm., sugar 20 mg per 100 ml protein 130 mg per 100 ml and chloride 570 mg per 100 ml

*Diagnosis and Treatment*—In view of the history the clinical state and the above-mentioned findings tuberculous meningitis was tentatively diagnosed Systemic chemotherapy and daily intrathecal therapy with streptomycin was begun Repeated lumbar punctures showed a persistently raised cell count much protein and little sugar (as little as 13 mg per 100 ml ) Cytological examination showed clumping of the cells on at least one occasion.

*Outcome*—The patient died in coma with anuria and jaundice twenty three days after admission

*Necropsy* revealed carcinoma of the stomach with metastases in the leptomeninges liver suprarenal glands, and lungs with associated silicosis, bronchitis, and emphysema. There was no tuberculosis. The meningeal involvement was confined mostly to the region of the basilar artery and the anterior surface of both cerebellar lobes. It was obvious on microscopy only to the naked eye it would have passed as a healing tuberculous meningitis. The rest of the brain appeared normal

These necropsy findings are exactly similar to those of McCormack et al (1953), who attribute the low C S F sugar level to the large demands of the active neoplastic cells for glucose

Carcinomatosis can only be distinguished from tuberculosis by finding malignant cells in the C S F This distinction is of importance because the recognition of carcinomatosis saves the patient from the rigours of intrathecal antituberculous therapy

My thanks are due to Dr E C Benn, consultant physician, Seacroft Hospital, for permission to publish, and to Dr W Goldie, consultant pathologist, for the necropsy findings

# RETROSPONDYLOLISTHESIS AS A CAUSE OF PARAPLEGIA

Robert Roaf
B M Oxfd, M Ch Orth Lpool, F R C S
ORTHOPÆDIC SURGEON, UNITED LIVERPOOL HOSPITALS

Retrospondylolisthesis in the dorsilumbar region of the spine is a well recognised clinical entity which causes local pain in the back and referred pain in the lateral aspect of the buttock There is often an associated degenerative arthritis of the hip-joint, this may make it difficult to determine whether pain in the region of the hip joint is due to primary disease of the hips or is referred from the spine

It is, however, unusual for retrospondylolisthesis to cause serious pressure symptoms and I have not been able to find any report in the literature of actual paraplegia being produced, so it seems worth reporting the following case Since treating this patient I have seen two further cases of retrospondylolisthesis with slight spasticity of the legs and it is possible th degrees of this condition are not uncommon

A married woman of 66, who was admitted to h April 20, 1954, had had pain in the lumbar region f years, and pain in the left hip for six years, with pr disability During the last two years she had bee walk only with assistance and inside the house, with k knees flexed For the last two years she had had inte urinary incontinence One week before admission t pital the pain in the left hip became worse and she b bedridden Her general health until recently had be but the pain had lately kept her awake and she h considerable amount of weight

She was a thin, rather querulous woman Both t knees were flexed to 90° and fixed Both legs were The tendon reflexes were not elicited, but there were plantar responses on both sides There was no d impairment of sensation The arms and cranial ner normal X ray examination showed retrospondyl of D12 and L1 Cervical myelography showed a complete block at the D12–L1 level (Lumbar my was attempted but was unsuccessful owing to ossif ligaments in the lumbar spine )

On April 27, 1954, laminectomy of D11, D12, and L performed The dura mater was found to be co at D12–L1, after laminectomy the constriction and normal pulsation returned below the level of th A fine rubber catheter could be passed up and down th without resistance

Postoperative progress was slow but steady from the day after operation Pain and cramp dis Spasticity gradually abated and urinary control Flexion deformities of the knees and hips had to be but she was ultimately discharged from hospital in Se walking unaided and only slightly spastic

## STIMULATION OF NATURAL IMMU TO ESCHERICHIA COLI INFECTIO

### OBSERVATIONS ON MICE

It has been recently shown[1] that differe virulence of *Escherichia coli* strains for mice correlated in vitro with the survival rate of the in the presence of mouse serum and complem this bactericidal system the avirulent strains were killed under conditions permitting 100% survival virulent organisms

During attempts to isolate the bacterial subst this reaction, a remarkable effect of the bac walls came to light After injection of 0 05–0 2 *Esch coli* cell walls, either intraperitoneally ( intravenously (I V), mice showed greatly susceptibility to *Esch coli* infection if challenged i 2 hours but greatly reduced susceptibility if the c was delayed for 24 hours This initial decrease resistance, followed in 24 hours by a great in believed to be due to the rapid neutralisation *Esch coli* cell walls of the normally effective serum mechanism, which within 24 hours is restored to level than normal

EXPERIMENTAL

*Preparation of Cell Envelopes*—Strains of *Esch Salmonella typhimurium* were used

They were harvested in saline from 24 hours nutrient agar The suspensions were heated at 60 C min and then centrifuged, washed and suspended to an approximate dry weight of 30 mg bacteria 10 ml of this suspension was shaken in the Mickle together with 5 ml of ballotini beads for 40 min[2] T beads and any intact bacteria were removed by centr for 20 min at 3000 r p m in an M S E minor angle ce The turbid supernatant was further centrifuged at

in a Serval high speed angle centrifuge for 1 hour deposited the bacterial cell walls These were suspended M disodium hydrogen phosphate and treated with w/w pure trypsin under toluene for 7 days, after which soluble material was deposited by centrifugation and d once with saline and once with distilled water before dried from the frozen state

*ulence tests* of *Esch coli* strains were carried out as hed previously[1] by I.P injection of dilutions of hallenge culture suspended in 1 75% hog gastric + 0 4% charcoal.

*alls* —The table shows the effect of injecting various ities of cell walls prepared from *Esch coli* 2380 on survival of mice after challenge with three virulent s of *Esch coli* It will be seen that 30 minutes injection with the cell walls of *Esch coli* 2380 may be killed by as few as 5 *Esch coli* whereas 0 organisms are required to kill a similar proportion rmal mice On the other hand 48 hours after ion mice challenged in the same way may survive al thousand times the dose lethal for normal mice is effect is non specific among *Esch coli* strains it t associated with any rise in the serum agglutinin against *Esch coli* and there is no increase in the of complement The immunity is at a maximum 2 after injection of the cell walls and has fallen to the al level about 5 days later The protection can be vely transferred by the serum of one mouse to her

e cell walls prepared from antigenically unrelated ent or avirulent *Esch coli* strains or from various s of *S typhimurium* all produce the same effects rying degree. Hence either a specific factor respon for this effect is widely distributed in the coliform almonella families or else similar factors occur in the ent members of these two bacterial species The *coli* factor is extremely heat stable biological ity being little impaired by boiling for 7 hours

hen 1 ml of unheated guineapig serum was treated 0 5 mg of *Esch coli* cell walls, at 37°C the comple titre was reduced from 60 hæmolytic units to and this decrease was shown to be due to the dis arance presumably by adsorption of the $C_3$ fraction mplement This pheuomenon is analogous to the val of the $C_3$ fraction when serum is treated with the t polysaccharide zymosan [2] In fact injection ice with zymosan will exactly reproduce the effects d here with *Esch coli* cell walls Moreover rats h are normally resistant to infection with *Esch coli* strains + mucin become susceptible soon after I P injection of approximately 50 mg of zymosan Thus six rats when challenged after 30 minutes with 100 000 cells of *Esch coli* 2380 + 1 75% hog mucin were all obviously ill after 24 hours and two of them died six normal control rats appeared well and survived

DISCUSSION

Most animals are capable of removing enormous numbers of *Esch coli* from their tissues both by phago cytosis and by serum killing If the cellular defences are inhibited by the presence of mucin the serum is still extremely effective in killing most *Esch coli* strains There is apparently an efficient serum system capable of acting on some substrate in *Esch. coli* cells, and it is natural that in acting upon the organisms the chemical system in the serum—whether enzymic or not—will be attached to and temporarily removed by the bacteria If the bacterial substrate can be provided in some form other than living bacteria the serum system will probably be adsorbed by it and given the correct amounts the greater part of the serum killing system might perhaps be removed so that its efficiency in destroying viable *Esch coli* cells would be seriously impaired and the animal would become highly susceptible to infection

Pillemer et al[4] have shown that treatment of various animal sera with zymosan at 37°C not only removes the $C_3$ component of complement but also removes another immunity factor which they call properdin[5] They have produced evidence that the bactericidal action of fresh serum is due jointly to its complement and to its properdin content When animal species are arranged in a series according to the properdin content of their sera this order corresponds roughly with the level of natural immunity of the species. Thus rats show the highest and guineapigs the lowest properdin titres More recently Pillemer has shown that injection of mice or rats with either our *Esch coli* skin fraction or with zymosan following the procedure described here results in an immediate fall in the serum properdin level to about 20% of its normal value the level is then rapidly restored and after 48 hours may reach a value four times higher than the original normal level[6] This finding suggests that the initial fall and subsequent rise in the serum properdin level as demonstrated by Pillemer following injection of zymosan or *Esch coli* cell walls, may influence or be the direct cause of the changes in resistance of mice to *Esch coli* infection as found in the present experiments If so it means that in the mouse under the experimental conditions used the predominat ing defence mechanism against this infection must involve properdin and complement. Whether or not this mechanism plays a part in other infections has still to be determined We may, however note that Pillemer and his colleagues have found that injection of zymosan into mice or rats greatly decreases their susceptibility to the bacteræmia and death which follow irradiation of the whole body[7]

Sir Almroth Wright repeatedly spoke of a "negative phase" following inoculation of humans or animals with typhoid vaccine This negative phase was demonstrated by a decrease in the bactericidal power of the blood lasting up to several days according to the dose of vaccine employed Where a small dose was injected a great increase in the bactericidal power of the blood was occasionally noted within two days of injection[8]

I am grateful to Prof Louis Pillemer of Western Reserve University Ohio for a gift of zymosan and for providing unpublished data I am also indebted to my colleagues—to Dr P D Cooper for the preparation of some of the *Esch coli* cell walls to Dr D. Hobson for a supply of zymosan, and to Mr C R Jenkin for technical assistance

## HYDROCORTISONE IN TREATMENT OF ALLERGIC CONJUNCTIVITIS, ALLERGIC RHINITIS, AND BRONCHIAL ASTHMA

HYDROCORTISONE has, in contrast to cortisone, a *local* effect in certain disorders of the skin and in arthritic joints We therefore thought it possible that it would have a beneficial local action on the mucous membrane in allergic disorders We briefly describe here the treatment with hydrocortisone of 4 patients with allergic conjunctivitis, 15 with allergic rhinitis, and 15 with bronchial asthma In all of these patients the disorder had been present for over a year, and in most for several years, and there had been little variation in the condition throughout the year—a factor which helped us greatly to assess the results

Hydrocortisone has only lately become available in this country In North America it has been found superior to cortisone in a number of cases of vernal catarrh,[1 2] and at least equal if not superior to, it in allergic conjunctivitis [3]

*Allergic Conjunctivitis*

Our 4 patients with typical allergic conjunctivitis, who had previously had local cortisone without success, were treated with daily instillations of hydrocortisone acetate (2 5 mg suspension in 1 ml physiological saline). 2 of these patients also had asthma and eczema, and were sensitive to various allergens For several years they had had continuous itching of the eyes and a viscous conjunctival secretion causing the eyelids to be glued together on waking The conjunctiva was slightly injected and had a milky œdematous appearance, particularly distinct in the lower fornix 2 drops (about 0 02 mg ) of the hydrocortisone suspension was instilled three times daily for two days

In the 1st case the symptoms disappeared completely for three weeks There was a recurrence after this time, and further treatment resulted in relief as before

In the 2nd case the symptoms were also relieved but recurred five days after cessation of treatment Continuous relief was achieved with a maintenance dose of 1 drop instilled every fifth day When an anti histamine drug was given by mouth at the same time this drop was required only every eighth or ninth day The conjunctivæ looked less red, but the milky œdematous appearance was still present

The 3rd patient, who showed the same signs but suffered only from excessive lacrimation, was treated in the same way and the day time lacrimation improved within forty-eight hours, after which there was negligible lacrimation at night

The 4th patient, whose allergic conjunctivitis was proved by the history and by conjunctival test to be due to cat fur, also improved under the treatment , but itching and redness did not disappear as in the first 2 patients

In the first 2 patients treatment was started with one eye only When there had been spectacular improvement of this eye both patients reported spontaneously that the other eye had also improved at the same time, but only partially

*Nasal Allergy*

The patients with nasal allergy had had rhinitis constantly for over a year All showed a typical swollen, boggy, mauve white, nasal mucosa In most cases the disorder was so severe that the use of decongestant drops could not be avoided , and in most local treatm zinc ionisation, cautery of the inferior turbinate, of polypi, or desensitisation had given no relief histamine drugs had, as usual, stopped running of the nose, but had left the swelling mucosa and therefore the blockage unchanged

These patients inhaled daily into their nos contents of a half or a whole celluloid capsule wi of hydrocortisone powder, from an Upjohn inhaler Every one or two weeks their nasal mu inspected A control period was obtained by the treatment for some weeks, or, in many case tuting an inert powder of similar taste for two weeks

In 11 of the 15 patients an important r improvement ensued They were able to breath through their noses and could either dispense a with nasal decongestants or limit their use to twenty four hours Shrinkage of the nasal was noted, but the boggy appearance and mauv persisted, except in 2 cases where the mucosa a normal in some places

In 1 of these it was thought likely that the norma of mucosa corresponded with those sites which w easily reached by the flow of the inhaled powd hydrocortisone was omitted the condition graduall ated in two to three weeks, but it improved two to th after treatment was resumed

In most cases treatment was started with on only, using the other as control , often the d obstruction was unequal, and the more severely nostril was selected for treatment first In th the improvement was sufficiently distinct to con previously " better " nostril into the " worse " t

In 4 patients the treatment was unsuccessful.

1 of these found the powder irritating to his nose and it In another patient a generalised urticarial rash within twenty four hours of the start of the treatme was abandoned Of the remaining 2 patients, 1 di the powder regularly

*Bronchial Asthma*

In the treatment of bronchial asthma the ch is the difficulty of depositing enough hydrocorti large surface area of bronchial mucosa It was to try inhalation of hydrocortisone powder with particle size of under 5 μ rather than inhalatio aerosol The amount of hydrocortisone powder through the mouth from a powder inhaler was or 7 5 mg per day

All 15 patients had perennial severe bronchial that demanded constant use of anti hist at bed time and of aminophylline or ephedrine the day In addition, to counter intercurrent spasm, they used an isoprenaline nebuliser 3- in the twenty-four hours Only those patien included whose condition had been stable for six months, and in whom the number of iso inhalations was approximately the same and this number was used to gauge the severity asthma After using hydrocortisone powder for three weeks these patients were given cartridge ing inert powder for the same period , after this them were changed back to hydrocortisone

In 11 patients the treatment caused definite ment of the asthma, the number of isoprenaline tions dropping to half or less When inert pow substituted the improvement persisted for up weeks, and when the asthma had returned to its severity resumption of hydrocortisone again relief An increase in the hydrocortisone dosage 15 mg per day did not cause further improveme

In 3 patients the treatment had no effect

The 15th patient had been on a maintenance dose of oral cortisone per day, and was using, in addition,

E H *J Amer med Ass* 1952 150 1660

no suppositories and 8–10 isoprenaline inhalations With this régime her condition did not vary for many hs When the 50 mg of oral cortisone were replaced mg of hydrocortisone powder a striking improvement red within two days. The number of inhalations dropped per twenty four hours and the aminophylline could be ed With 7 5 mg of hydrocortisone powder the condi was slightly worse than on 50 mg oral cortisone but 10 mg of hydrocortisone it was exactly the same and sage could be maintained at this level for many weeks

nce the systemic activity of hydrocortisone is at double that of cortisone[4] the effective equality mg of hydrocortisone powder with 50 mg of oral sone suggests a local action of the former In the majority of the cases hydrocortisone definitely oved the condition but did not completely abolish sthmatic obstruction

### DISCUSSION

r experience with local hydrocortisone in the ment of allergic eye nose and bronchial disorders o limited for definite conclusions about optimum ge and method of application and the type of patient likely to benefit most But we are sure that in these conditions it can be of therapeutic value Local treatment has the advantages that the need for large systemic doses of cortisone with the attendant dangers of systemic therapy, is avoided, and that it is more economical

We are indebted to the physicians of the chest department for access to their patients to Messrs Upjohn of England, Ltd for the supply of hydrocortisone powder and the powder inhaler and to Messrs Roussel Laboratories for the supply of hydrocortisone suspension One of us (H H.) was assisted by a personal grant from the Medical Research Council.

## al Health and Human Relations in Industry

Editor T M LING M A D.M Oxfd M.R.C.P., medical director Roffey Park Institute of Occupational Health nd Social Medicine London H K Lewis. 1954 Pp 265 21s

DUSTRIALISATION which has brought profound ges in individual and group relationships, is thought rry with it a higher incidence of psychological and hosomatic disorders. High rates of absenteeism, strial fatigue and accidents and sickness and osis are it seems, an almost inevitable part of rn society but perhaps they were of any society Mayo, as long ago as 1924 showed that the level roduction and the morale of a group of factory ers correlated more highly with their sense of rtance and responsibility to the community than the hours worked or the level of pay Since then ation has been directed to the study of the interionships of men and groups rather than of the e worker Many recent researches suggest that mployee often feels dissatisfied because he has no of belonging to a group or because he has no s. He feels insecure and frustrated and cannot t himself to his surroundings. The most satis ry industry is one composed of small primary groups e interests correspond with those of the concern whole

Ling has edited a collection of essays, by authorities ndustrial research and psychology dealing with al health in industry from many different aspects. imself suggests that wages and security prestige approval and the value and creativeness of the itself as well as the sense of belonging to a group eeds which must all be satisfied to ensure the mental h of industrial workers. In meeting these needs medical officer the psychiatrist the personnel ger and representatives of industrial management interdependent rôles to play—rôles which are fully ssed by the various contributors. This is a useful informative book

## Vitamins

*hemistry Physiology Pathology* Vol. II Editors: H SEBRELL, jun director National Institutes of Health Bethesda Maryland; and ROBERT S HARRIS professor of biochemistry of nutrition Massachusetts Institute of Technology Cambridge New York: Academic Press. 1954 Pp 766 $16 50

IE second volume in this new series of reference works e vitamins deals, in turn with choline the vitamins ssential fatty acids inositols the vitamins K nicoacid and pantothenic acid It is closely modelled on the first volume[1] and like its predecessor owes much to successful coöperation between the editors and contributors Each section on each vitamin has been written by an expert, yet overlapping has been largely avoided Although the main emphasis is on the chemistry and physiology of the vitamins their occurrence in Nature their pharmacology and the effects of deficiency in man and animals are also discussed, and on the whole a comprehensive account is given of present knowledge If the third and final volume reaches an equally high standard the series should be a valuable source of well documented up to-date information Both volumes are well printed and illustrated and carry author and subject indexes

## Foundations of Surgery

GEORGE PERKINS, M.C., M CH F.R.C.S professor of surgery London University Edinburgh and London E. & S Livingstone 1954 Pp 230 10s

Surgery for Toddlers' is the alternative title which Professor Perkins, in his preface offers for his useful and amusing little book It is intended for the student who has just finished his anatomy and physiology and is starting in that mood of relaxation which follows a major examination his first year of clinical work. Here is a small agreeable guide to the country which lies ahead something which he can read (and which, thanks to its dignified title he can be seen reading) in the train something which points out the main roads and gives him the lie of the land without luring him into fascinating but bewildering byways. It is written in short, brisk and often amusing sentences and it is full of memorable and important facts. Nothing could be better designed for warding off the slothful habits natural as Professor Perkins remarks to most medical students.

## Treatment of Acute Poliomyelitis

2nd ed Editor WILLIAM A. SPENCER M D department of pediatrics, physiology and physical medicine Baylor University College of Medicine Springfield Ill: Charles C Thomas Oxford Blackwell Scientific Publications. 1954 Pp 134 27s 6d

THIS small book summarises a course of lectures on the treatment of acute poliomyelitis, delivered at the South western Poliomyelitis Respiratory Center Texas

The 23 contributors represent all specialties associated with the disease—with the exception of anæsthetics which has not yet come to play much part in the treatment of poliomyelitis in the U.S.A Hence there is no mention of positive pressure respiration through a cuffed tracheotomy tube There is much else to be learned from these pages however The reader gains an instructive insight into an American

---

1 See Lancet 1954 ii 857

respiratory centre with all its functions, from nursing to biochemical studies There is a good account of glosso pharyngeal breathing by which the patient learns to force air down his trachea by a movement of his mouth and throat, pumping one mouthful after another into his lungs until they are well distended, and then breathing out Another interesting device is "the vacuum cleaner assisted cough" for respirator patients The positive end of a vacuum cleaner is led into the tank respirator in such a way that a positive pressure phase of up to 40 cm of water is reached The patient is taught to hold his breath as the pressure rises and then to cough at the highest pressure

Those who treat poliomyelitis will find in this book many such practical hints The first known record of a case of poliomyelitis—on an Egyptian plaque—adorns the cover

---

**Neuro-Ophthalmology** (2nd ed Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1954 Pp 591 £6 6s)—Prof Donald J Lyle's new edition is essentially a new book, about twice as long as the first, and containing some 100 more illustrations It has even been differently planned, the first half now relating many clinical anomalies to the anatomy of the eye and to the central and vascular connections of the globe, and the rest of the text being given to clinical entities with a rather broader basis Though the arrangement is not strictly logical, it has the merit of dealing adequately with clinical affections in terms of basic physiology and pathology The text is competent and the illustrations include many that are good, new, and distinctly original, though a few seem to lack point

**A Practical Manual of Diseases of the Chest** (4th ed London Oxford University Press 1954 Pp 647 84s)—Despite the great accumulation of new knowledge since the last edition, Dr Maurice Davidson and Dr John H have accomplished the task of revising this book minimum of important omissions and with some r in the number of pages A practical manual should only information that is fully substantiated and no versial, but the indications prescribed here for lung fall short of modern surgical practice, and the use of surely deserves more space than the effects of climat use of cortisone and of corticotrophin in sarcoid bronchial asthma has wisely been left for consid a later edition The book is carefully written and be produced

**Rötgenanatomische Grundlagen der Lunge suchung** (2nd ed Budapest Akadémiai Kiadó Pp 315 Ára 180)—This handsome and finely il volume from Hungary, compiled by Dr F Kovats, Dr Z Zsebök, is much better produced than any textbooks on radiology which have reached this It is to a large extent an atlas with cross sections and sections through the lungs related to the radiographs. The first chapters, on the anatomy bronchial tree and the segmental relationships, closely to Brock's work, which is suitably ackno The anatomy of the pulmonary vessels is worked angiography, but here there is not sufficient emphas wide intrapulmonary variations Identification of intrapulmonary structures by means of tomography attempted The best sections are those which show drawings the three dimensional levels of the bronchi an them to bronchograms All the line drawings and anatomical specimens, many of which are in excellent Many of the radiographs are poor, and not of the quality of the paper or printing Either the equipment or the film emulsion, or both, are inferior to

# New Inventions

## OROTRACHEAL CONNECTION WITH MINIMAL RESISTANCE

FIG 1 shows a new design in adult orotracheal connection intended for adults, to minimise resistance to breathing in clinical anæsthesia, and to reduce th intrathoracic pressure in patients with res paralysis due to poliomyelitis being treated with mittent positive-pressure respiration through endotracheal tube This reduction is achieved more rapid emptying of the lungs during the ex phase owing to absence of resistance

Fig 2 shows how a standard Magill endotrache is connected direct to the valve mount of a apparatus

Fig 3 illustrates how all the usual sources of have been removed, the lumen is gradually re kept smooth, and the size of the orifice is (actually 0 5 mm larger) to that of the tube it fits

The connections are made in three sizes, 8, 10, to fit tubes size 8 to 12 They are in two shapes with a 90° curve (fig 1*a*) for standard use, and a 135° curve (fig 1*b*) for operations about the he for poliomyelitis patients

The resistance to inspiration in these connect from a quarter to a tenth of that in common connections There is no measurable resista expiration, whereas in standard connections re expiration is much the same as that to inspiration

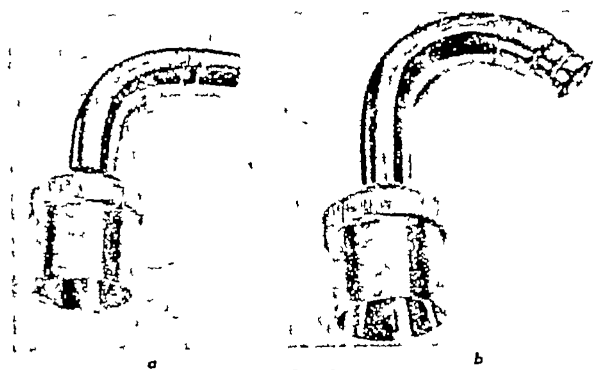

Fig 1

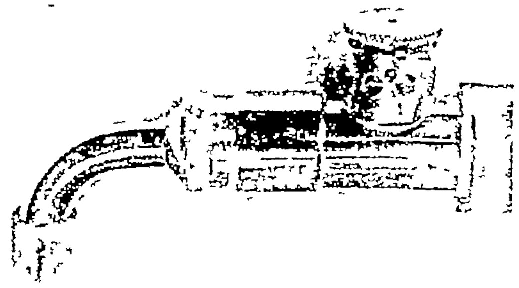

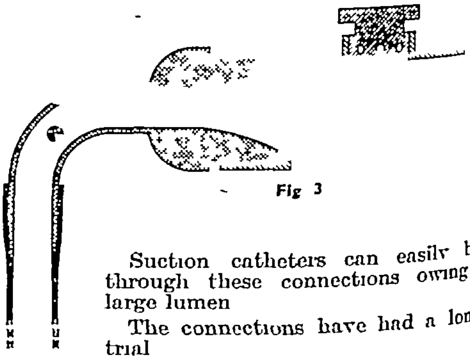

Fig 3

Suction catheters can easily be through these connections owing t large lumen

The connections have had a long trial

They are obtainable from Messrs Charles King L

Southern Hospital,
Dartford

## Total Gastrectomy

mortality of total gastrectomy is falling Until was 54%[1], now Marshall and Uram[2] find is just over 8%, compared with 35% in the 1927–43 In this decline there is danger for ns may be tempted to do the operation more and like all amputations it is not to be under lightly The only real justification for excising ole stomach is in an attempt to remove growth

A benign ulcer high on the lesser curve may mes call for section through the œsophagus t total resection results but in these circum a gastric tube can usually be fashioned from ater curve or even the distal half of the stomach o pyloric canal Again when at laparotomy it rtain whether an ulcer is benign or malignant gastrectomy may be inevitable for frozen s at the time of operation give little help since o difficult to interpret and the specimen may een taken from an area free of malignant cells ubmitting a patient to total gastrectomy it must ne in mind that though he may not become a nvalid he will no longer be the man he was y suffer from dysphagia due either to a disturb f the hiatal pinchcock with consequent reflux gitis and even pharyngitis or (particularly if n is present) to deficiency of the vitamin B x which Brain and Stammers[3] found in 9 of patients they followed up Sooner or later kely to become anæmic One thing is certain fail to gain weight and strength and may deteriorate in both these respects It is now n knowledge that this is due to steatorrhœa s of nitrogen in the fæces Kelly and nsteen[4] have investigated experimentally the effects on absorption of different types of mosis In dogs they made pouches from n and these proved satisfactory reservoirs not stem the loss of weight or prolong survival ound that only œsophagoduodenal anastomosis llowed by longer survival Welbourn[5] has that the fat loss differs little whether the œsophagus is anastomosed to duodenum or to jejunum and this disposes of the idea that fat is lost entirely because the pancreatic juices chase food instead of mixing with it As regards nitrogen loss Johnson et al[6] report a considerable improvement when food is enabled to pass through the duodenum When, therefore after total gastrectomy it is possible to join the œsophagus to the duodenum this should probably be done All else that can be done is to modify the diet Brain and Stammers recommend fractional' fat feeding for they found that weight was gained on hourly feeds of small amounts, but Butler et al[7] on the other hand suggest that the steatorrhœa be treated with a diet high in protein and sugars and low in fats, in particular avoiding fats containing saturated long chain fatty acids

An operation which induces such sequelæ must have substantial advantages in other ways, and these have not yet been established for total gastrectomy The evidence indicates that for carcinoma of the stomach this operation has no greater effect on survival than partial gastrectomy Finsterer's[8] longest survivors had been treated by partial gastrectomy and so had those in the 1486 cases reviewed by Stammers[9] but these patients were mostly operated on at a time when total gastrectomy was less common From their statistical data Walters et al[10] concluded that provided that resection clears the primary lesion (and for this purpose total gastrectomy is not always necessary) any recurrence is usually not in what remains of the stomach, but in viscera adjacent to it and elsewhere within or behind the peritoneum Though pancreas and spleen are sometimes included in total gastrectomy it is impossible to excise the whole potential field of metastatic deposit Marshall and Uram[2] who have studied 202 patients with total gastrectomy, of whom 184 had malignant tumours have also come to the conclusion that total gastrectomy does not increase the proportion of five year survivors and they recommend that it should be done only in selected cases Nuboer[11] has shown that in cases of carcinoma of the cardia an operation which preserves the distal part of the stomach will give a 35% five year survival It therefore seems that there is only one indication for total gastrectomy—when the growth involves so much stomach that the primary lesion can be encompassed in no other way—and this holds whether the aim is cure or palliation Regarding survival the crux of the matter lies in the extent not of the operation but of the lesion. If, by luck the lesion is confined to the stomach there is a chance of eradication by partial or total gastrectomy If the neoplasm has spread beyond the stomach any excision is in the nature of closing the door after the horse has bolted Even extensive excisions which include much of the lymphatic field and the parietal peritoneum spleen and pancreas may not succeed for from the stomach with its copious blood and lymph supply metastases are likely to be carried in all directions once either stream is entered

# Isoniazid Resistance

ISONIAZID RESISTANT tubercle bacilli behave oddly Some do not grow in the usual culture-media, and many are apparently avirulent in guineapigs and mice Certain strains require in their environment substances that have catalase or catalase like activity Such strains themselves are deficient in catalase, and COHN et al[1] found that this deficiency is closely related to the attenuation of the strain Thus, strains completely catalase-negative were avirulent in guineapigs, while catalase-positive strains were only slightly or moderately attenuated MIDDLEBROOK et al[2] investigated the catalase activity of cultures obtained from patients before and during isoniazid treatment They found that almost all highly resistant strains were catalase-negative Some sputum specimens yielded cultures which were less resistant to isoniazid, and these contained catalase positive strains that were pathogenic to guineapigs Some cultures clearly consisted of mixtures of catalase-positive and catalase-negative strains Since catalase-positive resistant strains were not isolated from any patients in whom treatment had been begun with a daily dose of 8 mg isoniazid per kg body-weight, MIDDLEBROOK et al recommend that this dose should be adopted, on this scale the dose for a ten-stone patient would be 500 mg, which is much greater than that usually given in this country MIDDLEBROOK et al admit that there is no "unequivocal evidence" that catalase-deficient strains are attenuated in man In fact, there does not seem to be any such evidence at all Isoniazid-resistant bacilli seem capable of producing disease KATZ et al,[3] for instance, reported a case of rapidly fatal tuberculous pneumonia in which a culture before treatment contained strains resistant to isoniazid and streptomycin Treatment with both drugs failed to alter the course of the disease The strains, which were highly resistant to isoniazid in vitro, produced disease in guineapigs, their catalase activity was not determined

The Medical Research Council workers have investigated the results of sputum-culture and sensitivity tests six to nine months after treatment with isoniazid was discontinued[4] 43 patients had resistant strains when treatment was stopped after three months, and 20 of these still had positive cultures at the end of a year On the other hand, only 3 of 22 with sensitive cultures remained positive This does not suggest that patients with resistant strains in the sputum become culture-negative more rapidly than those with sensitive strains, as might possibly be expected if resistant strains were less pathogenic in the environment in which they originated The character of the disease was different in the two groups, the resistant group containing more patients with extensive cavitation Without collapse treatment or resection these would be less likely to become culture-negative, and it is not stated whether either of these measures was applied It has been reported that isoniazid-resistant strains tend to disappear from the sputum after treatment has been stopped, and hence that the cultures have a lower level of resistance or become fully sensitive The M R C report does no this Although there were some differences b the sensitivity of cultures at the end of treatm six or nine months later, there was no clear e of general reversion It is sometimes f cultures of tubercle bacilli are heterogeneous tions, and sensitivity tests may record the resistance of only the most highly resistan in an unknown critical proportion Thus the isolation of strains resistant to streptomycin, salicylic acid, and isoniazid from sputum d necessarily imply that all, or even the maj the bacilli in the culture are resistant Only small proportion may be resistant to each combination of drugs, and most may be to all For instance, in the case reported b although strains resistant to isoniazid and mycin singly were isolated, growth of the completely inhibited by low concentrations of drugs together To explore the drug a culture fully would require many more tests than are at present done routinely, it doubtful whether the information obtained w clinically important enough to justify the work, but fuller quantitative investigation bacillary populations in sputum and in the p lesions themselves would obviously be valu research, and improved laboratory methods to increase the clinical value The medium MIDDLEBROOK et al,[1 2 5] for instance, is cl reduce the delay in reporting and make it e primary isolation to estimate the propor bacilli of different degrees of sensitivity A containing charcoal, developed by HIRSCH, claimed to give quicker growth and to be prepare and sterilise than media containing albumin, but so far this has not been t primary isolation

The bacillary population in the patient's l probably even less uniform than that in the s and its constitution cannot be determined examining the excretion of the bronchial tr is the lung a simple culture medium The requirements of isoniazid-resistant bacilli in th may be different from those in the lab Bacteriological investigations are easier t out and simpler to interpret than clinical and there may be a tendency for bacteriolog to be too readily accepted as guides to tr DRESSLER and MIDDLEBROOK, and their colle Denver,[7] have treated a group of patien advanced pulmonary tuberculosis by brief bed rest and early graded activity in add isoniazid with or without streptomycin The no evidence that treatment in hospital with rest in bed adversely affected the patients treatment was based on the "conviction th azid holds a unique position"[7] and that "the tion of isoniazid resistant mutants of tuber for guineapigs and rabbits must have significance"[8] Although unsupported by co clinical evidence, these convictions demand for there is no firm evidence that isoniazid nce has a similar significance to streptomycin nce Isoniazid resistant bacilli as we have said

## Slum Children Today

families of four or five live in one tenement room g the exhibits was a drawing of a bedroom little r than a cupboard, into which two double beds a cot could just be crowded ; here no less than eight ns slept, ranging in age from twenty years to or six

quotation from an editorial[1] on a London g exhibition in 1932, may be matched by one Miss Vera Poole s article on London slums in nchester Guardian of Nov 13, 1954

family of seven in three small rooms one room p entirely to the married daughter and husband remainder (six) sleep like sardines in two beds in er room "

verbal descriptions are reinforced by the figures Victor Freeman medical officer of health for on, in his annual report for 1953

ngton is not favoured with large open spaces and average of 76 2 persons per acre it is among the zen or so most densely populated boroughs in the of London no single ward can serve as a r other parts of the borough and in every ward the lon density exceeds the average for the County of 59% of nearly 82,000 Islington households o bath of their own and another 20% share a 53% of Islington households share even a water

ns that we have little to show for our twenty ears of slum-clearance and Prof Fraser ngton (p 244) explains how this has come Up to 1939 our schemes had resulted in the tion of a quarter of a million slum dwellings had all been replaced by better houses but ystem of exchange had unfortunately done g to reduce overcrowding Since then we have ny houses by enemy action and our population reased On the other hand thanks to much new g not associated with slum demolition we are first time getting abreast of the overcrowding n and even—taking the country as a whole— ing to get ahead of it. To increase this slight r even to hold it we shall (as he shows) have to ard and plan well

ne particular the picture has changed since 1932 se days all who lived in overcrowded squalid presumably did so from necessity , now Miss finds some do it from choice A single striking e from among several reported to her brings ome

nitary inspector called in to investigate a com of dampness, found an old house in a filthy state nily paid £1 a week in rent and their joint income 5 a week

es, in fact may grow up in overcrowded and ary homes and while they are at school their s are given statutory help in rearing them as one after another begins to earn and as some and bring home wives or husbands who are rning the family become affluent They will nsent to move into better quarters however, e they cannot be rehoused at the same rent they have got used to spending too small a proportion of their income on their accommodation One result is that others who have nowhere to live and little to pay, cannot even take over poor and cheap accommodation ' Not much more than a year ago ' Miss Poole reports ' a small local school had seventy of its children living with their mothers in night shelters ' Clearly it is absurd to subsidise rents for those who can afford to pay higher ones , and she suggests that housing authorities should use their powers more forcibly As those in condemned dwellings are evicted to make way for building so should the well-off families be moved from the slums, leaving for the time being the poor dwellings for the homeless or necessitous ' It is doubtful whether the housing authorities have the power to do exactly this but some way of getting round this difficulty should certainly be found in the interests of the children

The family of seven mentioned above have more than once refused to be rehoused on grounds of expense (they pay 12s a week rent) Most of the children have eye trouble because Miss Poole says while they were still at school the mother was not willing to lose time from work in order to take them to the clinic for treatment All are now earning and for the last two years the whole family have spent their holidays abroad (where admittedly they have relations)

With both parents at work children of school age spend a good deal of their time running about the streets but they are often expected to do the shopping and housework as well When they leave school and go to work even this amateur attempt at housekeeping goes by the board and despite a rising income the home becomes increasingly squalid But such financially prosperous families are not of course the only or most numerous residents of slums there are many people with young children living willy nilly under foul conditions Indeed conditions are inevitably foul where four or five families share a tap or a lavatory and use a common staircase which it is nobody s business to clean, where coal must be piled in the corner of a room, cupboards can be opened only if a bed is shifted and the slop pail and butter-dish are close neighbours Even more serious than such things as these is the effect on the physical mental emotional, and moral development of children of dishonest gross or terrifying neighbours

A family of six, known to Miss Poole, lived on the ground floor of a bombed house left in a state of disrepair On the floor above lived several men who boasted of thefts and illegal doings, used filthy language came in late at night, stamping shouting and singing bawdy songs and passed water on the floor above so that it dripped through the boards on to the terrified children in their bed

Life at close quarters with such ugly realities as drunkenness crime incest brothel keeping and the like damages the developing child in ways which we are only just beginning to recognise and assess As Miss Poole rightly comments rehousing is not enough human beings will have to be remade too She even doubts whether the modern policy of keeping the child in his own home—no matter how bad it is—is always fully justified A bad " dwelling may not matter much if it is illumined by the love of parents who do try to create a home however poor, for their children it is another matter, she suggests when the home is a filthy room into which the parents hardly ever come except to sleep The slum problem in fact, as the *Manchester Guardian*,[2] reporting the recent congress of the International Federation for Housing and Town Planning, pointed out, is still grave and pressing, and the question is how to make people in general aware of it

---

[1] *Maternity and Child Welfare* 193[illegible] 16 13.

We are at this time, Professor BROCKINGTON notes, rather well placed for getting something done, since the rate of growth of our population is slowing down, and our numbers in this island are likely within a few decades to become stationary or to decline In a hundred years or so, perhaps the housing problem will have gone into reverse how to demolish reinforced concrete at small expense will then be exercising the planners In the meantime children are being stunted morally and emotionally, as they were once stunted physically, by the pressures of their environment The ideal of one family one dwelling, put forward by BROCKINGTON, is worth attaining quickly As things are, we are not only exposing our coming generation to harm we are laying on ourselves the onerous and costly task of remaking them as citizens

## Annotations

### OCCULT UNEMPLOYMENT

THE preregistration year, it is said, may take 15–18 months to complete[3] The time is lost mostly between the two house jobs, and, whereas formerly the newly qualified could put this "spare" time to good use by acting as locum tenents in general practice, now, without registration, any work outside hospital is barred to them.

This is a serious loss to the community Just over 2000 were provisionally registered in England and Scotland in 1954, and if 3 months is taken as the average excess over the working year required to obtain registration, then an equivalent of 1000 six month house jobs is being wasted annually If all 2000 could be more continuously employed the shortage of junior hospital staff would be felt much less acutely Considered in terms of highly skilled hands kept idle, the present position represents an unrewarding expense for the nation No business would permit the waste of such a valuable capital investment

How can the position be improved? The starting dates of jobs need to be related to the graduation days of universities and colleges Universities hold graduation days at different times, and, with many other faculties involved, they cannot be expected to fall into line with each other But most of the newly qualified take up appointments in their own teaching hospital or its surrounding region, so regional synchronisation would be fairly satisfactory Perhaps appointments to teaching hospitals should be made a short time before those to regional hospitals, in order to give unsuccessful applicants for teaching-hospital posts the opportunity of securing an appointment in the region without much loss of time Secondly, a proper appointments bureau is necessary—one central place in each region fully informed about the jobs that are to be had This is a function which many medical schools could fulfil more satisfactorily than they do at present

If in fact the average is lost about three months, regional boards might be asked to adjust the dates of appointments—though such is the inflexibility of the terms of the 1950 Act that an amending Act might be needed to enable the General Medical Council to register those whose six-month jobs were curtailed in the change over Nevertheless Governments will sometimes respond where man-power wastage is adding its toll to man-power shortage

### COSMETIC PROBLEM OF ANOPHTH

REMOVAL of an eye sets a difficult cosmetic
which has not yet been satisfactorily solved.[1]
ately evisceration or enucleation is often l
junior staff After his socket has healed the
referred to an artificial-eye clinic, where a
supplies a concavo convex prosthetic shell wh
well and will be retained comfortably within
The resulting appearance is satisfactory only
with deep set eyes Critical patients rightly
that their new eye has neither the expression
appearance of the other eye, it occupies an
position and does not move

The normal eye rests on a sling of fascia
from the medial and lateral orbital walls This
ligament is formed by a thickening of Tenon's
the fascial envelope which surrounds the eye
of the extra ocular muscles and the lids pr
*dislocation of the eye, and the orbital fat forms*
behind it When the eye is removed the vol
orbital contents is greatly reduced, and the
ocular muscles adhere to each other and oblit
muscle cone The fat in the upper orbit thus
drop, and so the lower fornix accommodates
cushion of fat at the expense of the upper, whose
is greatly increased The usual prosthetic shell
ported in the shallowed lower fornix by the
orbicularis muscle of the lower lid, and in time
may become lax and everted because of the w
it bears The upper margin of the prosthesis rest
posterior limit of the enlarged upper fornix, so
to lean backwards, and the upper lid lacking the
of the normal eye may droop, with a sunken
above In the more fortunate cases the twitchin
fibrosed mass of extra ocular muscles at the
the orbit imparts some movement to the
cosmetically this is seldom adequate

The ophthalmologist's first difficulty is to
the eye with an implant which will keep the
fat and muscles in a nearly normal position
often been attempted, and many materials
introduced into Tenon's capsule glass, celluloid
peat moss, agar agar, rubber, wire, silk, catg
paraffin wax, and rabbit's eyes have all been
Smooth spheres of acrylic resin or of gold prov
reaction but tend to migrate Spaeth[2] reco
Guist's carbonised bone ball, because the
reaction which it causes firmly fixes it in its
location But, in truth, nothing seems really

Secondly, the ophthalmologist must provide
ment of the prosthesis by linking it somehow
implant Cutler[3] tackled this by inserting a
shaped acrylic implant with its opening facing
over which he closed Tenon's capsule, mus
conjunctiva These tissues were drawn at
into the basket by a button sutured to the
of the basket When healed the button was
and the conjunctiva remained dimpled The
had a peg which fitted into the dimple and thus
with movements of the implant But the
undergo pressure necrosis or may not form a
permanent concavity, and the long term results
much better than with spherical implants. Other
used *partially buried implants*[4 5] The co
covered the implant, leaving an exposed
which the prosthesis peg fitted accurately
ments of these prostheses were excellent, and
technique the lower fornix was relieved of the
of the prosthesis But Choyce[6] followed up 99

uch implants and found that 45% were extruded three years because of infection He thought it ble that few such implants would be in situ five after insertion and for this reason he recommended tinuing their use

ing[7] has had an original idea for solving the tic problem He removes the contents of the eye ecures within the empty sclera an implant which ns a magnet the prosthesis also contains a et Young's implant maintains the structure of the in its normal state and the magnetic attraction plant to prosthesis imparts a full range of move Furthermore he relieves the lower fornix of n by the implant s magnetic support of the pro Young claims that his prosthesis which is thin not be removed more than once a month though es not state on how many cases he bases this usion If the long term results are satisfactory others can make his rather complicated method this technique will constitute a major advance

## ILDREN S HOSPITAL TO BE CONVERTED ?

RECOMMENDATION to the board of governors of ry s Hospital that the Princess Louise (Kensington) tal for Children should be converted for use by patients focuses attention once more on the ing pattern of supply and demand in the hospital es. The development of maternity and child e services, the advances in medical knowledge and ique and the improvement of economic and social ions are combining gradually to reduce the number spital beds needed for children and though this ituation must be a source of satisfaction and pride concerned it also raises the question of which beds to be retained and which can be used for other ees.

County of London has ten general children s als with a total of about 1000 beds and there are bly another 1500 beds in the children s wards of hospitals in the county This gives a ratio of 75 en s beds per 100 000 people and though one remember that London hospitals draw patients far beyond the county boundaries this provision atly in excess of the 50 per 100 000 suggested by o and Taylor in their estimate of the needs in astle[8] On this score it therefore seems probable a reduction can safely be made in the number of en s beds in London and the arguments put before Mary s board by its subcommittee are convincing far as they relate to diminution of need On the hand the subcommittee s proposals for dealing this situation by closing one of the children s tals are more debatable Some would say that it be better to preserve and develop the children s tals as centres of paediatric treatment and education o reduce instead, the number or size of children s in the adult hospitals serving the same catchment even if the hospitals concerned are not controlled o same boards or management committees The bility of doing this is not discussed in the sub ittee s report but it will no doubt be raised by the al s medical staff committee who are putting their ions to the plan before the governors

making their recommendations the members of bcommittee were properly influenced by the board s tion to provide facilities for clinical teaching and e relative pressure upon the hospitals under the s immediate control From this restricted point w the beds in the Princess Louise Hospital may be luous and so may those of several other of the on children s hospitals the majority of which are parts of teaching hospital groups Nevertheless se children s hospital have traditions and achievements of which they can be proud and before the drastic and controversial step is taken of converting any of them to other uses it would be prudent to develop more fully the arguments for and against the preservation of children s hospitals as such and to review as a whole the situation of children s beds in London. To make such a review is perhaps beyond the scope of any one of the 30 different boards and management committees that control the children s hospitals and children s departments of adult hospitals in London but it should be made before any final decision is reached

## TRANSFUSION OF BATTLE CASUALTIES

IN the latter part of the 1939–45 war blood loss was generally regarded as the most important cause of shock in battle casualties Usually the degree of shock was closely related to the volume of blood that had been lost but occasionally shock was more severe than might have been expected In some such cases the patients did not respond well even to generous transfusion and a few died The question of how many of these might have been saved by even more lavish transfusion has remained unanswered.

In Korea during 1952–53 belief in the importance of restoring and maintaining the blood volume after severe injury led to freer use of massive transfusions of blood Up to 30 pints of blood was given within twenty four hours of injury much of it after bleeding had been controlled Prentice et al[1] using the blue dye T 1824 or red cells labelled with $Cr^{51}$ studied the changes in blood volume after operation and massive transfusion in 53 severely injured men In 43 the initial body weight was known and their normal blood and plasma volumes could be calculated In only 3 cases did the blood volume rise above normal values—in 2 after 7 litres and in the 3rd after 1 5 litres, of blood Of 25 patients of known weight studied with $Cr^{51}$ 11 had blood volume deficits of less than 15% after transfusions averaging 3 187 litres in the other 14 the deficit averaged 32% after transfusions averaging 6 74 litres Despite these large deficiencies only 3 patients whose volume deficits were 38% 43% and 52% showed the clinical features of shock Of the 18 weighed patients whose blood volumes were measured with dye 14 had deficits of more than 15% the average deficit being 31% after transfusion averaging 7 785 litres; yet none showed clinical signs of shock, and all did well after operation

When the patients were grouped according to the sites of their wounds the importance of muscle injury became clear In wounds of the limbs there was almost always gross muscle injury and large volumes of blood were needed during resuscitation and operation Yet after operation nearly all these patients had a blood volume more than 15% below the calculated volume and their average hæmatocrit was 30 6% On the other hand patients with abdominal wounds who had received similar volumes of blood had postoperative blood volumes more nearly normal and an average hæmatocrit of 45 8% Prentice et al found that when large masses of muscle were injured large quantities of blood were normally required for resuscitation But it is remarkable that in a 78 kg man with a traumatic amputation a blood volume of 2 6 litres on admission rose only to 5 1 litres after an uneventful reamputation with minimal blood loss and the transfusion of 10 5 litres of blood In a similar case a transfusion of 3 litres raised the blood volume only from 2 5 litres to 3 0 litres It seems unlikely that much blood was lost into the tissues damaged at operation In abdominal wounds blood loss is chiefly due to damage to vessels in the intestinal wall and mesentery; and bleeding into the peritoneal cavity must be directly and accurately controlled by li at operation In wounds of masses of muscle in the limbs it is impossible to control all bleeding-points at operation, and the most that can be done is to ligate the obvious, larger vessels, after operation a good deal of blood is lost into the muscles in the margins of the excised wound, and there is always considerable postoperative swelling of the less severely damaged muscle in the region of the wound Whether this accounts for the lowering of the blood volume by a third found by Prentice et al is uncertain, but it seems the most likely of their three possible explanations for the discrepancy between blood volume and the large quantities of blood transfused They have shown that it is unlikely that blood is trapped in parts of the vascular system and is not measured by the methods they used, or that hæmolysis of the transfused or recipient's cells was so extensive as to account for the large deficits

---

[7] Young J H Ibid 1954 38 93

[8] Spence J C Taylor M D Lancet 1954 i 719

[1] Prentice, T C., Olney J M Jun., Artz, C P., Howa Surg Gynec Obstet 1954 99 54

Of the 53 patients 3 received more than 10 pints of blood and 9 more than 20 pints, yet after transfusion the average deficiency in blood volume was 25% As the total volume of blood transfused increased so did the discrepancy between the volume administered and the subsequent blood volume, and this difference involved both red cells and plasma Blood volume did not rise later during recovery, as might be expected if blood had been sequestered during the acute changes after injury and operation Prentice et al suggest that further evidence may be obtained by weighing patients before and after resuscitation, in addition to measuring blood volume

At first sight this report suggests that most severely injured patients are inadequately transfused and that in future much larger volumes of blood should be given, but this impression may not be wholly correct After transfusion and operation most of the patients were in good condition despite reduced blood volumes, and as the amount of blood transfused increased so did the discrepancy between this and the final blood volume It is conceivable that much of such large transfusions may be lost into injured tissues and be metabolised there In severe infection and in peritonitis [2] blood volume may remain persistently depressed despite large transfusions of blood or plasma The cause is presumably disturbed vasomotor control, and a similar disturbance may follow severe injury

## SMOKE AND SULPHUR

We are all by now thoroughly convinced that smoke fog is a bad thing—destructive to life, health, and materials, light obstructing, dirt-begetting, and enormously expensive We owe warm thanks, therefore, to those who have demonstrated how much harm it does But it is perhaps a little disappointing that so much of the research in progress is still directed towards amassing more and more gloomy statistics about the effects of atmospheric pollution As Sir Ernest Smith said to the National Smoke Abatement Society last September,[3] "it should not be necessary to wait for absolute proof from statistics before tackling all the problems of atmospheric pollution in a comprehensive way"

As the Committee on Air Pollution (the Beaver Committee) [4] made clear, there are two main components in smog—namely, dirt and grit, and sulphur products The committee concluded that if this (or indeed any other) Government would declare for a clean air policy the dirt and grit could be abolished fairly quickly Thus it could be reduced by making much more smokeless fuel available for domestic grates, by popularising appliances for the economical burning of these fuels, by introducing modern plant, better methods o and a wider use of gas and electricity in indust better control of smoke from railways, by esta more smokeless zones and also smoke control a which the use of bituminous coal for domestic would be restricted), and by more effective (to be enforced by local authorities) against the of black smoke Such a programme might ve give us a sparkling—though not necessarily atmosphere in a very few years

But the sulphur products—the invisible more dangerous component of smoke—pres difficult problem The total quantity of sulphur discharged into our air is over 5 million tons a and at present we know of no really satisfactory preventing its discharge One straightforward pr measure would be the better cleaning of coal at t heads so as to remove as much sulphur as possi the National Coal Board is pressing on with a pr to achieve this, but only a small part of the be removed in this way by existing methods It possible to add some material to coal which woul the sulphur to be retained in the ashes, attempts this have not so far been successful, but further r might well give the answer Fuel oil, used in r and to drive some vehicles, also releases sulphur i air, but, though it is technically feasible to most of the sulphur from fuel oil, this is a costly p In large power stations sulphur dioxide can be from the gases, and such processes are used Battersea and Bankside stations, though not de The cost of installing new plant in other st Beaver Committee estimated, would add 8s to th of converting each ton of coal into power, or 0 unit of electricity generated—an addition which scarcely be dismissed as inconceivable At a discussion of the Beaver report, held by the Inst Fuel on Jan 21, this figure was challenged by M Peattie, deputy chief engineer of the British Ele Authority he thought the cost of intr washing into power stations would be at leas million and might be £250 million—which, h would increase the cost of electricity by 12% E expenditure, however, might well be justified committee's estimate of the damage done by air p in a single year was £250 million

His was the only critical note in a meeting pro Beaver Mr G E Foxwell, D SC, immediate president of the Institute, and a member of the Committee, suggested that our present difficult the fact that the National Coal Board and the gas are hesitating to expand smokeless fuel p because the Government have not accepted a policy, while the Government are hesitating to this policy because they are not sure whether, if the nationalised undertakings would be able to r additional demand for these fuels In an att break this deadlock, Mr Gerald Nabarro has int into Parliament his Private Member's Bill—the Air Bill This will come up for its second re Feb 4, and it embodies all except the fiscal mendations of the Beaver report It is a measure Dr Foxwell hinted, has been compared by so *spur to goad the Government to action*, and by o a pistol likely to go off at half-cock In Mr N own view, he said, the Government have no inte introducing legislation during this session a any measures to deal with air pollution would be till after next November, and probably fill t Parliament We should all like to see someth before that

One further reason for spending money on ne that the sulphur which is at present such a liabilit become an important asset Even the method ng used at Battersea and Bankside result in the rge of sulphur effluents into the Thames—an urable practice in itself and a shocking waste of modity which is always valuable and sometimes

---

[2] Theron P H Wilson W C *Lancet* 1949, i 172

[3] The Coal Crises and Society Published by the National Smoke Abatement Society 30 Grosvenor Place S W 1 Pp 10

[4] London H M Stationery Office 1954 See also *Lancet* 1954,

At Fulham power station before the war a d was used which retained the sulphur as impure m sulphate but this method was given up during ar and has never been started again A new and er process, on trial by the British Electricity rity gives ammonium sulphate as a residue but ears are rolling by without any report appearing s method and the Beaver Committee remarked hey were not impressed by the speed with which matters have been pursued Perhaps some ive to speed might be offered

thing is abundantly clear we must agree as a s to spend more money on this problem To doctors sed to spend whatever is necessary seems urgent ven from the strictly economic standpoint there are arguments against the present conversion of so precious coal into useless smoke. Money spent on ering ways of preventing so much waste and ge may be expected to repay itself many times over

## CROWDS AND POLIOMYELITIS

a group of epidemiologists were asked to predict ffect of large crowds on a poliomyelitis epidemic replies might not be unanimous They and others herefore be interested in a careful account of what ned in a situation of this kind.[1] Western Australia, the most sparsely populated areas of the Common h experienced its biggest recorded poliomyelitis mic last year The only epidemic of comparable n this State had been in 1948 and on that occasion athering of crowds was thought to have had an se effect on notification-rates

t year's *epidemic* coincided with the arrival in rn Australia of the Queen and the Duke of Edin , and huge crowds were expected throughout the The public-health authorities felt justifiable alarm he possibility that the crowds would allow the mic to spread and enlarge Precautionary measures attempt to reduce the spread of infection in crowds, aimed largely at children A special review of ren which would have involved mixing of children many different areas, was cancelled Instead en were assembled in their own school groups at l points on the highway of the Royal route ren were not required to stand about for longer an hour and each child was given a health bag ining food a drink, a cake of soap a small towel his or her own drinking vessel School groups kept carefully apart from each other but no l measures were taken to control the size of adult s General control measures were already in opera Clinical cases of poliomyelitis were isolated for weeks and close contacts under the age of 15 were at home for the same period There was a publicity aign on the importance of hand cleanliness, and ier on anti fly measures *Dental operations* tions on the nose and throat and immunising ions were suspended and swimming classes were lled

e Royal couple arrived in Western Australia just the peak of the epidemic, and crowds of sizes ecedented in the history of the State gathered every f the following week These crowds were extremely s and yet the steep downward trend of the notifica rate was quite unaffected This can hardly have due to exhaustion of susceptible individuals for onths after the epidemic peak there were still over tified cases a month—a figure regarded as within the mic level for Western Australia

We are left with the possibility that crowds are not an important factor in the spread of poliomyelitis or that the precautions prevented increased spread Nature is an untidy experimentalist, and because of the absence of controls in most of her trials it is almost impossible to assess the importance of different factors Nevertheless either conclusion would point to transmission of infection by fæcal contamination as more important in this epidemic than spread by pharyngeal droplets This is in line with the seasonal incidence of the disease and with the higher concentration and longer sojourn of the virus in the intestine than in the pharynx The experience of the Western Australians has valuable lessons for epidemiologists everywhere

## NATIONAL FORMULARY

THE 1955 edition of the *National Formulary* will be welcomed by both general practitioners and pharmacists for whom it is principally designed This volume retains the general structure of its predecessors and an admirable dogmatic survey of current pharmacological teaching will be found as before, in its opening pages The formulæ themselves represent a wide range of prescribing traditions The Joint Formulary Committee announces that its policy has been to retain a prescription even if its justification on pharmacological grounds is disputed provided it is still in common use This spirit of leadership from behind explains the retention of many favourite prescriptions but not the *rejection of the* pill of aloes the emulsion of liquid paraffin with agar or the compound thymol mouthwash But room has to be found for many new preparations and something must go one can imagine that each of the 62 deletions cost the committee a pang The capsule of quinalbarbitone and the tablet of isoniazid are welcome newcomers but it is strange to find among these mist. gent alk c phenobarb and tab quinin bisulph

In the 1952 *Formulary* each preparation had a Latin and English title in that order whereas the section headings had an English and a Latin title in that order Consequently the pulveres were sandwiched between cataplasma and the liquores This arrangement, according to the new preface proved inconvenient to the users *of the Formulary But now instead of adopting the* obvious solution (as in the *B.P* and *B.P C*) of finally displacing all Latin titles to a position of inferiority, and calling all things by their plain proper English names the committee has turned the clock backwards Poultices are now followed by collodions and these in turn by nasal washes The main titles of preparations are given in abbreviated Latin displeasing to the eyes of those who read Latin and meaningless to those who do not The *Formulary* contains a pharmacological classification but in its present form compressed into 15 consecutive pages, this is little more than an additional index The classification would be much more valuable if its sections were dispersed throughout the *Formulary* proper which would then be a suitable companion volume to the modern textbook of clinical pharmacology

Meanwhile these criticisms should not obscure the general excellence of the book which is a sturdy monument to the British tradition of compromise If publication of it were to cease its sternest critics would be among the first to protest The *Formulary* is to be distributed to doctors next month Distribution also to clinical students might greatly encourage rational prescribing with a *corresponding decrease in the national drug* bill

## Public Health

# HOUSING

## FROM THE FIRST WORLD WAR TO THE PRESENT DAY *

C FRASER BROCKINGTON
M A, M D Camb, D P H.
PROFESSOR OF SOCIAL AND PREVENTIVE MEDICINE IN THE UNIVERSITY OF MANCHESTER

THE story of housing is one of the most dramatic and poignant in our social history Two of our most cherished beliefs—the ideals of health and of property—have been brought into conflict over the issue of the sort of home in which we should live It has been a struggle waged, as it were, between giants, and fought on shifting sands As property rights slowly conceded point by point the right to State intervention, the demands made on the score of health increased in step, as the measures to combat slums gained in cogency, the increase in population and the rise in households continually tended to neutralise their success In the background of the contest lay the bogy of overcrowding, worse perhaps than the slum itself, which was made greater by slum clearance

Looking back at the seventy years preceding the first world war, one may ask why so much legislation over so long a time had so little effect The trouble lay mainly in the failure to meet four fundamental difficulties (1) the inflated cost of building land, (2) the need to compensate owners of demolished slum property, (3) high rents of new houses, and (4) the difficulties of slum-clearance in circumstances where populations and households were ever expanding When great overcrowding and widespread slum conditions are present together, the administrator who presses for the demolition of the slum, unless he also provides the equivalent in new housing, ipso facto, increases the overcrowding From the frying-pan into the fire, some would say Nor was the obvious truism always appreciated that in the slums live the poor The costs of new housing are so high that rents, if unsubsidised, are beyond the pocket of the slum dwellers Legislation that takes no account of these fundamentals must always be a dead letter Such increases in new housing as there were took place chiefly by trends and influences independent of Parliament Such houses were not for the unskilled and semi skilled workers, whose lot remained largely unaltered In any event, the increase in the number of households was sufficient to occupy all the new dwellings built under private enterprise

To all this was added the difficulties of advancing standards The number of dwellings needed rises as the number who can be supposed to live properly in a home goes down The difficulty of providing them becomes greater as the standards advance

### The Inter-war Period

The first world war left the state of housing graver than before By 1921 we had reached 8,739,197 households, and $3^1/_2$ million persons were living, in England and Wales, at more than 2 per room In Scotland the figure for overcrowding was 43 3%, with 21% at more than 3 per room. But as we enter the period between the wars we find increasing evidence of a new outlook The Housing Act, 1919, required local authorities to prepare schemes for providing in their areas enough homes for the working classes and at first the Government gave unlimited aid, by paying excess cost over a 1*d* rate But the enemy of increasing cost soon gained the upper hand the 1923 Act limited Government aid to
tribution of £6 per house per year for twenty
that of 1924 (the Housing Financial Provi
to a subsidy, with restriction on sale, of £9 for
years in urban areas and £12 10*s* in agricultural
Between 1918 and 1931 over 1 million houses were
three quarters of them under government
schemes, and between the wars the grand total
4 million homes The volume of house buildi
1930 rose to an average of over a third of a
a year

The Housing Act of 1925 left much to be desir
it stimulated the first real efforts at slum-cl
and those of 1930, 1935, and 1936 made a valiant
to deal with the remaining difficulties The
removed the liability to compensate owners of
houses when these were made the subject of a de
order It required houses to be provided in
for clearance areas, thus removing another great
to action, and it introduced a new procedure
"improvement area"

In 1935 overcrowding was at last officially
This was on a low rating roughly similar to the
room scale used by the Registrar General for
forty to fifty years in his Decennial Census Auth
were required to survey their areas and report
extent of official overcrowding

The 1936 Act brought the legislation to its
state The responsibility rests with the housing
ties, as it has done since the beginning, to insp
districts, the authorities have the power,
appeal to a county court, to order unfit houses th
be made fit at reasonable expense, to be repaired
ing to a schedule of work Houses that cannot b
fit at reasonable expense may be the subject of a
for demolition or closure, Any areas consistin
least two houses may be declared a clearance
a clearance order can be submitted to the Min
Health for confirmation, there is provision for re
ment areas, which has extended the idea of the
ment area to include all property in a given are
there is authority for compulsory purchase orders,
with the power for making by laws. Al
applies to houses that are occupied, or are of th
suitable for occupation by persons of the
classes

It was unfortunate that the Housing Act
allowed a variable standard of fitness to continue,
that of the "general standard of housing accomm
for the working classes of the area"

The rate of clearance accelerated By 1939
of a million houses had been demolished and
had all been made good by replacement hous
much of the benefit of the vast slum clearance
through the overcrowding which remained W
second world war this intense activity came to
and all further attempts to destroy slum propert
left to the enemy

### After the Second World War

The post-war period has been one of intense
activity, unassociated this time with any atte
remove the slums, and accompanied by a new
to town and country planning Since the war
2 million houses have been built, five eighths of
local authorities, and 124,555 in temporary

ing separate accommodation. This includes the red and single adults who nowadays more often to live alone.

idea of planning the use of land was first intro in 1909. The 1919 Act required all boroughs and districts with over 20 000 people to produce a e of development. Again and again Parliament l measures (in 1923 1925 1929 1932 and 1935) ied to strengthen the control of land but with real effect. Only 5% of England was by this means subject to a planning scheme. With the second war however real appreciation of what was d for control began to grow up. In 1943 a separate ry of Town and Country Planning was created— ng the Government's acceptance of the belief that planned use of land was ever to become a reality ld only be as a result of action on a national scale Barlow, Scott Uthwatt Reith and Hobhouse formed the basis of a new machinery. The Towns Act 1946 was followed by the Town and ry Planning Act 1947. Twelve new towns have been d and the planning authorities—now limited to the councils and county borough councils 145 in or—have been preparing schemes for their areas.

### The Present Position

lay we hear more complaints than ever but they out of an awareness of what good living demands of se. It is only in the past fifty years that internal ing sanitary convenience and bathrooms have to be considered a general need. The Housing f 1923 was the first to require a bath in a new ng and that of 1924 a bathroom. Our present ards owe much to the work of the Central Housing ory Committee appointed under section 135 of lousing Act of 1936 and to the *Housing Manuals* 44 and 1949 which this committee produced. To 44 manual we owe the 16 point recipe for the making healthy house. The Housing Act of 1949 has seen nd of varying standards of fitness according to tate of the working class property in the area. as extended the jurisdiction of the housing authority lly to all property. We have also come at last to ciate that overcrowding is more damaging to comfort, and enjoyment than is the insanitary of the dwelling itself.

housing today falls far short of the ideal.

*owding*

rcrowding is still a serious consideration. Accord the 1951 census 11.6% live at a density of between $1^1/_2$ per room 4.9% between $1^1/_2$ and 2 per room between 2 and 3 per room and 0.4% over 3 per (For the purposes of the census rooms counted he usual living rooms including bedrooms and n but excluding sculleries landings lobbies closets bathrooms.) Improvement in official overcrowding between the 1931 and 1951 censuses had been ectedly high. The average of persons per room has from 0.83 to 0.73 in England and Wales and from o 1.01 in Scotland. The percentage living at more 2 per room has fallen from 6.91 in 1931 to 2.16 51. In the 1931 census there was only one London gh with less than 5% of the households living at per room. There are many areas (e.g., in and around astle and Glasgow) where overcrowding is still a. The average density per room in Glasgow is and a recent survey of 718 families rehoused for years showed an average density of 2.03 per

t overcrowding is more serious than these figures at. The official figure for overcrowding which is roughly 2 per room is too lenient. The figure of the Royal Commission on Population is 1 per room. At this rate there were just under 3 million households holding over $13^1/_2$ million people, overcrowded in 1951. Further to this overcrowding affects the family and particularly the large family. Overcrowding increases steadily with family size. 44% of families with 5 persons has less than one room per person; the figure for 6 in a family is 72% and for 8 in the family 93% according to a special survey quoted in the report of the Royal Commission on Population. This rise of overcrowding rate with family size takes place equally within the same income group. We have also to remember that many more households although not technically overcrowded, live an overcrowded life. The chief cause of this is lack of warmth which may cause 3 or more to crowd into a bed or 5 more more to a small room.

The effect of overcrowding in the absence of other adverse factors are in 1954 not easy to assess. Housing is one of a number of factors which play their part in the spread of infections of the respiratory type. When other important adverse influences are absent, overcrowding on its own may be relatively unimportant as the cause of illness. But when other things are not equal over crowding in an unhygienic house may be the determining factor. It is thus with tuberculosis once an open case occurs in a house secondary infection of children becomes more common. It is thus also with infant mortality and infections of childhood. But much the most important effect of overcrowding is its destructive influence on an ordered family life. No true home life can be lived in an overcrowded house.

*House sharing*

Overcrowding is objectionable and can lead to physical mental and moral ill health. Sharing of dwellings is no less an evil. It is itself a cause of overcrowding and a potent source of mental strain. Over 2 million house holds in Great Britain (1951 1% census) are shared, $^1/_2$ million of these are also overcrowded (that is living at more than 1 per room). Sharing bears heavily upon those with young growing families and particularly upon the newly wed. In a recent Aberdeen study of women who booked a bed for a hospital delivery over half of the total and about three-quarters of the primigravidæ shared a home. The most inadequate and often insanitary accommodation can be preferable to sharing. Insecurity worry and unhappiness are the results of the conflicts which arise.

*The Poor Home*

The outlay required to get a roof over your head varies with the choice and area and structure. Good housing in a healthy area will generally cost more than a slum dwelling to rent. The significance to the family budget of this simple fact is considerable. Children cause poverty and poverty is the chief reason for the poor dwelling. Large families suffer particularly. As the family grows and the weekly pay packet has to be stretched to meet increasing liabilities the parents before sacrificing food seek relief in cheap clothing and less expensive housing. The large family naturally gravitates to the cheapest sort of house. An alternative is to increase the family income by taking in lodgers or sharing. The growth of the family is probably one of the reasons why in the Aberdeen survey council houses occupied by such families were more commonly shared (78% as compared with 38% of private dwellings). Council houses were also more often overcrowded (29% as compared with 14%). Indeed any influence that takes away the element of elasticity in the budget may do harm. In the M'Gonigle survey at Stockton-on-Tees the suggestion first appeared that re-housing could be harmful to health if the cost of housing was too great for the budget. The flexibility of cheaper housing was

---

erguson T Pettigrew M G *Glasg med J* 1954 35 153 removed Soutar, Wilkins, and Sargant Florence[3] said of the Birmingham survey

> “While providing a much better environment the housing estate undermines the family's resources in other respects The family moving from the slums to a new housing estate on the edge of the city has greater costs to meet out of the same income Rent is usually higher, there are increased costs of transport both for business and pleasure, and often the necessities of illness, there is usually a need for more furniture, necessitating hire purchase agreements, wear and tear on clothing, especially on footwear, is generally greater, children's appetites are increased, food prices are higher *To accentuate these higher costs there is sometimes* a reduction of income due to women losing the opportunity for part-time work in the city As an independent social reform, rehousing has its limitations”

### *Lack of Equipment*

Despite the big housing drive, many of our present houses are obsolete Out of our total of about 11 million houses, nearly half were built before 1914 and 3 million before 1870 In the matter of housing we are living in the past The 1951 census recorded more than 1 in 5 households (22 7%) without exclusive use of a water closet and twice this number (45%) without exclusive use of a fixed bath More than 1 in 10 (13 8%) are without exclusive use of both sink and stove For the 57,700 households with more than 3 persons living per room the present situation is grossly inadequate, 52% of these are without exclusive use of a piped water-supply, 41% lack exclusive use of a cooking stove, 80% of a kitchen sink, 84% of a water-closet, and 92% of a fixed bath 84% of these overcrowded homes lack exclusive use of both stove and sink There are 2 million households (2,078,800) sharing dwellings, irrespective of the number of rooms occupied, that present a similar picture, the percentages of inadequacy (64, 39, 49, 69, 86, 50) being very similar to the houses living at 3 per room In half of these shared dwellings, where the household lives in one or two rooms, the percentages of inadequacy (78, 57, 69, 86, 94, 70) are almost terrifying in their completeness The term “living” in such conditions is an exaggeration Even to consider the usual inadequacies of bedroom space, furnishing, the absence of a pantry, a broom-cupboard, or proper space, heating, and lighting, with room for children to study, and the many other essentials of decent living, seems fantastic in the light of such conditions

### *The House in its Social Setting*

Many of the social needs of the family should be satisfied within an area that can be conveniently reached The satisfaction of many of these will be found in the town The town, therefore, should be a pleasant place in which to live and a joy to visit it should shelter the good life That it ceased to be so during the hundred years between 1750 and 1850 is one of the heavy prices we have had to pay for industrialisation “The idea of the town,” the Hammonds said, “as a focus for civilisation, a centre where the emancipating and enlightening influences of the time can act rapidly and with effect, the school of social arts, the nursery of social enterprise, the witness to beauty and order and freedom that men can bring into their lives, had vanished from all minds” The town was no longer “a living personality, expressing and cherishing the instincts, tastes, beliefs and corporate pride of the citizens widely and richly pictured”[4]

## The Way Ahead

Bad as in many respects housing is today, our towns are immeasurably better than the civilian barracks and camps of 1850 Nevertheless, when one thinks of other achievements of our vast industrial mach balance sheet of a hundred years of housing encouraging

Perhaps the greatest hope of improvement li static population Britain, having battled its w two centuries along a dynamic demographic is now entering upon a period of stationary lation For some time to come—possibly fo years—this island will return each year to the Re Generals' departments a population figure of 50 million During the last twenty years or *independently of rising population*, the numb separate households has much increased, beca smaller families and the greater numbers of persons living alone This source of increase, likely to disappear With the old enemy halted we can overcome him completely The present d for new housing, if continued, should be overcome the present shortage, of which shared d is the most obvious sign, in a relatively short of time, and it can then be applied to the of the slum itself There is of course much to but in a static population and without the tion of increasing households the task is well our capacity We will be wise to remember the of Lord Simon of Wythenshawe in the 1930s worst living conditions are not to be found in slu in the overcrowded larger houses let in lodgings shall also be wise to continue to let new buildin priority over slum-clearance

Nevertheless, the time has come to look b immediate needs Quantity has necessarily taken of place in our thoughts we have needed so the roof over our head But now that the ideal family, one dwelling, is at least within our gra should turn our attention, without delay, to quality should seek to provide for the good life by enri interior of the home and by adorning its social se

### *The Home*

It is not for me to talk about architectural detail I will only speak of the home itself As Mack says, “In dealing with ordinary families, planning too often been a dull, routine matter of figures, to family size, and houses and flats are acc built with one, two, three, or more bedrooms in to certain mechanical calculations”[5] To think in of persons per room, as now we are inclined to often to ignore the meaning of family life Our aim be to provide what is needful for a home, including diverse objects as hobbies for father, and a roo study and quiet for grammar school children We aim at good insulation and proper space heating can now make it possible to use every room for older folk and single workers, every home have three bedrooms A newly married couple, *family to start and to carry through*, and later children's friends to put up, can look forward occupation of a three bedroom house for a cont spell of thirty years The home must cease to woman's workhouse Good planning and the technical aids, which the New World has sp can release her from drudgery The framework of services from space heating to clothes washers, be mass produced, freed from the exp inadequacies associated with lack of uniformity made available to all at home The house must be than a reluctant and passive partner in family E should be an active, willing, and friendly particip

### *The Town*

One of the most important needs of a good social is that there shall be an easy access to a cultural eed good towns If this was true in the 17th century much greater the need today when we have become ion of town dwellers Good towns were relatively o produce when this country had a population of e 8 million people and a strong rural economy he proper balance of town and country is im ly *more difficult with 50 million and a strong* industrial economy Yet it is not impossible l is the great enemy and must now be strongly ed

The curse of religions is their tendency to make people e that certain systems of doctrine and certain cere s contain in themselves the whole secret of the universe educing the vast and wonderful to the small and childish tunately when human nature functions without religion kes exactly *the same mistake* The blight of modern ology is its tendency to think that when names are to various aspects of human behaviour a great advance ds wiser conduct is thereby made Similarly the nce of priesthood is to-day found all too frequently g scientists and notably psychiatrists. The nature of iverse and of man is in hard fact infinitely complex and ntely mysterious it makes ridiculous those who d to know all the answers whether they do so in the of God or of science —*Observer* editorial Jan 16

## HEALTH EDUCATION

The education of the public in matters of health is no new practice but whereas formerly it was haphazard and desultory it has now become methodical and systematic Yet even in this country there is evidence that it should be intensified

David[1] showed that in Greater London people were surprisingly ignorant about tuberculosis—although there has been more propaganda about this disease than any other Half those questioned thought that tuberculosis was hereditary and a third either believed it to be non infectious or did not know whether it was or was not Gore and Hartston[2] recorded very similar findings Likewise a survey among women has revealed prejudice and ignorance about the causes and the treatment of cancer[3] Public ignorance—and apathy—are suggested by the tardy response to clean food campaigns the high home accident rate the continued vast expenditure on 'patent' medicines and the low rate of immunisation against diphtheria (It is estimated that *in the London area in 1953 only 51% of children* under 5 years of age had been immunised against diphtheria at any time[4] whereas the aim is immunisation of 75% before the age of 1 year)

Walker[5] speaks of the prevalent ignorance about medical science but does not doubt that today people are *more responsive to propaganda than formerly Partly this* improved responsiveness may be due to the experience of the many who were in the Services in the late war when a vigorous health-education campaign contributed *substantially to the ultimate success* of our arms Much of the most telling propaganda had its birth in the units themselves where it was fostered by the commanding officer and his officers with the medical officer as counsellor Some may recall too the posters and road signs on the highways of North Africa and Southern Europe Blood toil sweat and tears: why add Malaria? Mepacrine a milestone to victory' and others less polite. The obvious loss of man power through malaria dysentery typhus and other diseases was one of the most effective of all health propaganda weapons And contrariwise, in civilian life today one reason why rates of immunisation against diphtheria and smallpox are dangerously low is that so few parents of young children are old enough to remember the time *(not so long ago) when diphtheria was a serious menace* while still fewer know from experience what smallpox can mean But some of the Army's other educational weapons could certainly be more widely adapted to civilian conditions—for instance, with the managing director cast as the commanding officer and the works doctor as his counsellor

A W H O expert committee which has been examining this problem[6] recognises that health-education programmes can conform to no standard pattern the programme must be specifically designed for the locality As to methods the committee rightly criticises the long lecture which seldom secures continuous attention, and whose *effects fade rapidly* The lecture is slowly being ousted by the discussion group and panel discussion Films too have an important place but the committee points out that these may produce a passive mental state and in any case they should portray local conditions. Pamphlets and posters are increasingly used but they are quite costly and the committee sensibly suggests that if used at all they should not be put up simply as decorations and should be changed often. Similarly, health exhibitions may not justify the financial outlay unless they are followed at once by further local propaganda.

[4] Report of London County Medical Officer of Health 1953 See *Lancet* Jan. 8 1955 p 93.
[5] Walker J A *Med Offr* 1954 92 331
[6] Expert Committee on Health Education of the Public First Report *Tech. Rep. Wld Hlth Org* 1954 no 89

The report makes it clear that the aim of health education should be to encourage personal responsibility. In this country the Services continue to play an important part by training National Servicemen in hygiene and health. But we should now be concentrating on younger people, in pre school and school days.

### Vital Statistics for 1954

The Registrar-General's provisional vital statistics for England and Wales for 1954[1] show that the birth-rate was 15 2 per 1000 population, compared with 15 5 in 1953 and 15 3 in 1952. The infant-mortality rate was 25 5 per 1000 related live births, the lowest annual rate ever recorded in this country; this rate compares with 26 8 in 1953, 27 6 in 1952, 29 7 in 1951, and 52 8 in 1938. The death-rate was 11 3 per 1000 population, compared with 11 4 in 1953 and 11 3 in 1952. R births exceeded registered deaths by 171,334

### Influenza

In the 160 great towns of England and Wal were 134 deaths attributed to influenza in th ended Jan. 15. In the three preceding week had increased steadily, the figures being 56, 82, Since the week ended Oct. 2 there have been 64 from influenza in the 160 great towns; the corres figures for the three previous winters were 200 (1 426 (1952–53), and 261 (1953–54). Laboratory in tions continue to confirm that many outbreaks to influenza B, though isolated cases of influ have been identified in Wales and the Midlands

### Smallpox in France

A message dated Jan. 14 from the French mi public health and population gives the number of smallpox in the Vannes area as 44, of whom died (later press reports put the number of dea Contacts have been placed under strict surveilla mass vaccination has been carried out in the The latest cases appear to have been direct previous cases

## The Widdicombe File

### XXII ὁ βίος βραχύς

MY DEAR BILL,

Mrs Wayneflete has just died. Admittedly 83 is a good age and everyone will say she had a good innings, but I still feel sad. What a pity she didn't call you earlier instead of letting her daughter, who, as a one time nurse, surely should have known better, go on applying hot fomentations to an obvious epithelioma of the vulva. When my house surgeon finally got the history, we found that the original small swelling was first noticed *fifteen months ago*, and although it was at first thought to be simply a boil—and it obviously became infected very early—the fact that it grew bigger and bigger should have convinced her daughter that it was a most unusual boil! I believe the old lady herself resisted the suggestion that anyone should examine her, so the daughter, I suppose, is not wholly to blame, but they both became alarmed by the first hæmorrhage. You saw the specimen—I keep a coloured slide especially to show the students as a "horrible example."

As you know, I did a very wide excision of which even Stanley Way would have approved, but she had a local and pelvic recurrence rather less than a year later and from that moment went down hill very quickly indeed. Still, she did have about a year of reasonable comfort and I am quite sure the operation was justified.

I saw a very similar case in which the mother in-law of a surgeon had a melanotic sarcoma of the labium major which she had *known* about for eight months before seeking advice. Only a local excision to relieve the bleeding was possible, but in spite of the limited surgery she survived, spent a very happy six months in Devon—"down tu Budleigh Salterton"—and then mercifully succumbed with dramatic suddenness to secondaries in the lungs.

I expect you see tragedies just like this in your own practice—I only see the gynæcological ones, which are bad enough—and it does seem, on the face of it, that the public do need some education and reassurance about cancer.

And yet it is astonishing how hard it is to convince people—men, women, doctors, public authorities, even Government departments—of the necessity for *some kind* of health education. Stocks, in his "Studies in Medicine and Population Subjects" of 1950 produced some very alarming statistics. In the first place, of the 86,000 people of both sexes who die each year of cancer, 2 in 3 50 years of age and 1 in 5 is under 45—it's by no means a disease of the aged—and of these, ca of the breast accounts for about 1 in 5 and of the and adnexa for about 1 in 10. The tragedy women is that Stocks found that the avera between the onset of symptoms and the comm of treatment was six months for breast and t ten months for body of the uterus, which is enough reading.

Malcolm Donaldson analysed these statist further and showed that for carcinoma m "delay period" of *under* six months meant that 3 cases were stage I or II, and therefore more ame treatment, and in any case gave over 40% five ye rate.

In our own unit, we see about 50 cases of carc the cervix every year. Of these, 6% are stage I a are stage II. In not one of five major centres in F was the percentage of stage I carcinoma of the less than 11. The figures from the eighth annua on the Results of Radiotherapy in Carcinoma uterine Cervix (Stockholm 1954) show that, of cases analysed, 19% were stage I and 40% The five year cure-rate of 26,555 cases treated latest five years was 62% for stage I and 43% for and it was only 8 5% for cases in stage IV, who rep 1 in 13 of all cases seen. In 1955 it is still true to of all the cases of carcinoma of the cervix we se 1 in 3 will survive for five years. In our own se 1 in 4 at best.

It is quite obvious from this evidence that the the women come for treatment the better are our of helping them; so the delay must somehow be The Central Council for Health Education has t objectives: (1) to reduce this delay between fir toms and attending a doctor, and (2) to reduce th between reporting the symptoms to a doctor an effective treatment. Which seems reasonable Both the women and the doctors need ginger believe, for in my own experience not every menopausal bleeding" is sent to hospital by the at once.

Why should there be these delays? Some the mental state of the woman prevents her seek advice. Either she is ignorant of the significance symptoms, or she is so afraid of cancer that she to be told it *is* cancer in her own case. I alwa the students that all women are liars and all wo fools, which gets me into much trouble, altho force of the argument is never more fully shown these very cases of cancer in women. It does se women must be educated somehow to recog dangers they run in neglecting early and p

cant symptoms—the question is how I know
agree that wholesale propaganda would be worse
less and only increase the dread of cancer that
oman has but it is equally futile I think to say
y attempts at education would *introduce* fear of
I believe the dread is there already You read
valuable report, full of interest and significance

t 21 040 *letters to general practitioners* asking
whether they thought education of the public
cancer would be of value 4831 replies were
l (about 24%) and of these 2148 gave an
fied Yes,' and 2683 an unqualified No
these *figures it was deduced that general practi*
were *not* in favour of cancer propaganda But
quite rightly pointed out that such a deduction
y misleading and in fact a misuse of statistics
fact, more than three quarters of the doctors didn t
the letter at all and only one doctor in *eight*
said 'No Lord Horder in reporting the
of the inquiry said that the Campaign expresses
itude to the General Practitioners in the country
ying in such large numbers This is an index of
erest which the problem arouses I never quite
ood why a 24% reply was considered a tremendous
s, while the fact that three quarters of the doctors
reply at all seemed to me to be an index of their
*nterest* in this vitally important matter

you there is a lot of opposition to the suggestion
medical officer of health should preside over any
tee to implement the scheme contained in the
y of Health circular (18/53) encouraging local
ties and voluntary bodies to initiate exploratory
s in cancer education For this and other reasons
failed completely to get a scheme started but
York and Manchester pilot schemes giving such
gement we must try again I am completely
ed it s worth it particularly when I remember
ayneflete

# In England Now

*A Running Commentary by Peripatetic Correspondents*

NOWADAYS when public-school fees are so high and when about a third of the local rate is spent on education it is interesting to recall how some parents arranged for their children s education two hundred years ago

A gardener who became a nurseryman and later a small farmer sent his son, then about six, to a small school about a mile distant and later found a young teacher to teach this elder and his younger son nearer home With him they learnt to read English tolerably well and to write a little Gilbert, the younger was too young to profit as much as the elder Robert who soon became remarkable for his fluency and correctness of expression and read the few books that came in his way with much pleasure and improvement Their education continued thus three years when the little seminary was broken up by reason of the master obtaining a superior situation elsewhere

The farmer then instructed his sons himself He conversed familiarly on all subjects with us as if we had been men and was at great pains as we accompanied him in the labours of the farm to lead the conversation to such subjects as might tend to increase our knowledge or confirm us in virtuous habits He borrowed Salmon s *Geographical Grammar* for us, and endeavoured to make us acquainted with the situation and history of the different countries of the world So wrote Gilbert the younger many years later My father had been a subscriber to Stackhouse s *History of the Bible* and from this Robert collected a complete knowledge of ancient history An uncle seeking a copy of *The Complete Letter Writer* obtained instead a small collection of letters by the *most eminent writers with a few sensible suggestions for* obtaining an easy epistolatory style This book was to Robert of the greatest consequence It inspired him with a strong desire to excel in letter writing while it furnished him with models by some of the finest writers in our language

My brother was about thirteen or fourteen when my father regretting that we wrote so ill sent us, week about during a summer quarter to the parish school that we might have an opportunity of remedying this defect ' In the next year we learn of the boys becoming acquainted with Fielding and Smollett with Hume and with books on English history In the following year their former tutor became English master at a nearby school and the elder brother revised his English grammar with his former master After a week the harvest intervened but he returned later for two weeks, during which time he learned French bringing home with him a French dictionary and grammar and the *Adventures of Telemachus* in the original In a little while by the assistance of these books, he had acquired such knowledge of the language as to read and understand any French author in prose This was considered as a sort of prodigy Acting on advice to try Latin in like fashion, he purchased the *Rudiments of the Latin Tongue* but finding this study dry and uninteresting it was quickly laid aside and this completes the account of his (Robert s) school education excepting one summer quarter some time afterwards that he attended the parish school of Kirkoswald to learn surveying

The father was William Burness (for so he spelt his name) a native of Kincardineshire The elder son Robert was born at Alloway in Ayrshire on Jan 25 1759

* * *

The *National Formulary* born by economics out of war has won a sure place in the doctor s bag ; and on the pharmacy shelf it stands in proud dilapidation beside the scarlet and gold *B P* in its fresh splendour Why isn t it fatter ? asks the doctor who hopes that it will prove a convenient source-book for most of his prescriptions. Why isn t it thinner? says the student— though he is likely to go on to grumble at the omission of radioactive isotopes I suspect that the Formulary Committee could have produced as many different formularies as there are county cricket clubs They must have known moments of anguish in deciding what to drop Preparations that they *have* dropped are listed in the new edition like loyal servants honourably retired and so doctors can catch by the coat tails an old friend on the way out, by writing, for instance, Solv Hydrarg Perchlor *N F* '52

The committee cannot hope to please everyone all the time But in its choice of pollarded Latin for titles of preparations it runs the risk of pleasing hardly anyone at any time Competent classicists will shudder at the hideous mutilation of a fine language, and the medical student will wonder why the committee cannot march in step with the compilers of the *B P* and *B P C* by opting for good plain English Anyhow, jubilation will be unconfined in the Potteries, whose craftsmen still make a whole range of receptacles embellished with the truncated Latin titles of obsolete Galenicals.

* * *

Our pooser hole was made to aid our latest cat whom we took because she was on the way to the gas chamber Our problems were the same as those of your correspondent last week, but now we have a two-way flap of hardboard which looks decorative and stands out at 45° with the slightest wind In cold weather the house gets icy We have had to increase the lagging on all the pipes and buy a special low-wattage anti-freezer for the water tank All is not on the debit side however, because when we bought our new puppy it was small enough to use the same hole Training was easy, but we are paying for it now because the hole is too small and the puppy won't bark to be let out She just sits in front of the hole on one side and because she can't get out won't let the cat in from the other

Our present problem is fairly simple—whether to spend the money on further insulation if we enlarge the hole or just wait and buy a new carpet later The cost seems to be about the same

* * *

Life in most hospitals passes quietly, and any minor departure from routine, such as the ejection of the residents' piano from an upstairs window, is liable to hit newspaper headlines Our latest claim to fame began with night sister's discovery of an unwanted man in the sluice For reasons still not quite clear, the resident obstetric officer was summoned to deal with her attendant vasomotor phenomena, and, since resident obstetricians tend to spring from a small-statured race, our colleague saw fit to bear a long stretcher-pole under his arm for protection Meanwhile the intruder had vanished without trace and the police decided to bring their bloodhound into action A large, sad-faced animal called Pluto was duly brought to the scene of the incident, but, overwhelmed by a host of new smells, he shook himself violently, chased his tail a few times, and made off in the direction of the labour ward where he barked loudly at a placenta lying in a bowl The commotion woke the babies in the nursery, who all started yelling at once Pluto took to instant flight and, after a careful search, was discovered ten minutes later in the grounds, digging a hole The sergeant who had long since despaired of finding the right scent, then announced that he would take the dog for one last frisk before retiring to the station This was a good cue for making some tea, and with Pluto contentedly munching an underdone sausage from the night-nurses' supper, a good time was had by all

* * *

The patient's complaint was worms—alleged to be three to six inches long and wriggling Suggestions for treatment were many Worm powders and drenches perhaps unreliable and difficult to administer Someone proposed waiting till night time when the worms come out, and then transfixing them or seizing them with dissecting-forceps He must have been a little mixed in his zoology, perhaps he was thinking of threadworms Another method considered was to bang on the surface with a hard object, the worms then come out to see what is going on, and can be grasped firmly This is too unkind to the patient The best suggestion so far is to send for a thrush This is not an example of one disease driving out another I forgot to mention that the patient is my lawn

## LEUKÆMIA AND ANKYLOSING

SIR,—A conference was recently convened Medical Research Council to consider new inquiring into the causes underlying the the death rate from leukæmia At this memorandum was presented drawing apparent association between leukæmia and spondylitis This information was based on limited number of instances, and the memb conference considered it very desirable th evidence should be collected on this possible association of leukæmia with ankylo litis is a curious one, but it may well be one that noted in individual patients by some of your

Dr W M Court-Brown, a member of the External Scientific Staff, at present working Department of Medicine, The Postgraduate School of London, Hammersmith Hospital, is collecting the relevant data on this subject. be very grateful if any of your readers who witnessed the occurrence of leukæmia in suffering from ankylosing spondylitis would him

Medical Research Council,
38, Old Queen Street,
London, S W 1

## MENTAL HEALTH AND PUBLIC HEA

SIR,—I welcome the fact that this subject raised in your leading article of Jan 15 It *not generally known that the curriculum for the* in public health as laid down by the General Council is no rigid set of rules and that men appears as part of both the preliminary and final the time which may be devoted to the subj left to the discretion of the teaching body which the course of instruction It is thus possible fo prehensive course in mental health *to be* this curriculum

In Edinburgh we do make a serious attempt of a series of lectures, demonstrations, and keep our students abreast of modern knowledge health and social aspects of mental health

I agree that “What is there to teach an an important question There is no room for co about what is already known concerning ment A substantial amount of what goes into is invalidated hypothesis, stimulating as a further research, but in itself not enough what is being done in other countries and much is now taught under the name of mental hygiene more than early treatment What is urgently is research into problems of prevention of mental who are the vulnerable members of the co how can they be found? and how can we help

These are the most important points, but have raised the question “Who is the proper visiting *and education in* a mental health I should like to comment on it The health by her vocation and early training as a sick general wards, quite unsuited for the task and training does little further to equip her to field of mental health The suggestion that she informed about these matters than the pub *doctor* is untrue for Edinburgh *and I* should be if it holds elsewhere In my opinion a more person for this type of work would be a social worker or an unspecialised social wor suitable supervision, but even their training improved for this purpose

## TUBERCULOSIS IN IMMIGRANTS

Dr Doig's observations (Jan 15) on tuberculosis young people of the island of Lewis are most ng and I have no doubt that the high incidence culosis in Irish emigrants to England is also due minimal, undiscovered lesions which they take em, or to reinfection in England and not as d Macdonald[1] have suggested to any undue bility to infection Emigration from Ireland to the U.S.A Australia and New Zealand has ing on constantly since the end of the war and here have not been any reports of a similar e of tuberculosis there In order to be admitted countries it is necessary for one's lungs to be ically normal but tuberculin tests are not done would seem that if an Irishman has a normal ph of his chest at the time of emigration bility does not matter greatly

and Macdonald accepted the type of lesion in sh patients as evidence of recent primary infection rength of Wallgren's[2] time table of tuberculosis time table is applicable only to children and s it is rarely possible to decide the time of infection by studying the lesion alone

adults tend to develop relatively acute lesions pleural effusions and exudative infiltrations even if e been tuberculin positive since childhood Extreme of this phenomenon are described by Rich[3] who it that although the adult African typically contracts progressive type of disease which suggests a recent infection at necropsy evidence of healed childhood s very commonly found Another extreme example teration in the type of lesion which is a result of tivation. In Europe during the war acute tubercu the rule and this was related to the environment to the tuberculin state of the patients. On the and, Rich and others have shown that primary sis in the adult may be indistinguishable clinically reinfection type of disease My own experience of y district of Northern Ireland suggests that pro- primary tuberculosis in adults is extremely uncommon ems quite reasonable to suppose that the unfavourable ings in which Irish emigrants find themselves in are enough to account for the rather florid disease ey develop

k however that it is in their invocation of the miological phase of tuberculosis in Ireland that d Macdonald go most seriously astray

believe that because of later acquaintance with sis the rural Irish have less resistance to tuberculosis e English This argument is difficult to follow in those parts of Ireland where there is a high pro of negative tuberculin reactors there is a lower osis death rate than in Southern Ireland as a whole d Joyce[4] found in County Roscommon only 14·5% in positive at the age of 18 Admittedly only 69 of this age were tested and these are not representative e county but there would seem to be some indica many young adults there are susceptible to infection ative tuberculin reaction is taken as an index of ility Furthermore Flynn and Joyce assume (I am te correctly) that the number of tuberculin negatives sing from year to year; yet in 1943 the tuberculosis te in County Roscommon was 100 per 100 000 and it was 20 But apparently the epidemiological in 1943 was more favourable than 10 years later there were more positive tuberculin reactors in 1943 rate of 100 per 100 000 as recently as 1943 indicates y widespread tuberculous infection has existed in h countryside and it is impossible to see how a n by nearly 75% of this death rate in 10 years can stent with an increasing susceptibility to the disease ms fair to presume that the deaths in County Ros have followed the usual trend of a falling tuberculosis death rate towards the upper age groups. Yet at the age of 30+ Flynn and Joyce found that 66·6% were tuberculin positive although here again the number of persons tested was not an adequate sample It is most probable that in Roscommon deaths from tuberculosis are not *occurring in* the traditionally susceptible tuberculin negative young people but in the traditionally resistant tuberculin positive mature middle aged or elderly adults The same is true of all communities from which tuberculosis is receding There are large areas of the U.S.A where the tuberculosis death rate is negligible where scarcely any of the children or young adults are tuberculin positive and where the deaths are mainly among *the elderly* who having spent their childhood in a time when tuberculosis was prevalent are the most likely to have been exposed to infection early in their lives Conversely in populations with high tuberculosis death rates there is always a high proportion of positive reactors, and a high reactor rate in children is always associated with a high death rate in young adults. It is wise to remember that no community has yet controlled tuberculosis by tuberculinisation of its members In any country where 100% of the people are tuberculin positive it can be guaranteed that tuberculosis will be the most important cause of death

It seems to me that the 'virgin soil theory of tuberculosis is plausible but quite fallacious and unable to withstand critical analysis Destructive tuberculosis is a disease of tuberculin positive people and acquired resistance while it may influence the course of the disease in individual patients does not seem to exert any significant effect in preventing new cases We must face this fact if we are ever to resolve the vast perplexity of the immunology of tuberculosis

## IMPOTENCE

SIR —Dr Tuthill (Jan. 15) seems to me to deserve great credit for putting forward an original logical and therapeutically valuable way of looking at cases of impotence I do not see cases of impotence but it is one of a group of conditions such as enuresis in which physiological pathological and psychological mechanisms are interwoven Of the last physiological and pathological superficial and deep primary and secondary factors are often difficult to sort out It is often necessary to explore some way along physical lines then for simple psychological causes returning if necessary to look for rarer physical causes and then again returning if need be to look for deeper psychological causes Some of the patients who failed to reply to Dr Tuthill's questionary may well have needed deeper investigation but he has shown that approaching the problem physiologically often gives speedy and lasting help It would be of interest to hear the views of others with experience of treating dyspareunia and the results of their methods and it is also to be hoped that Dr Tuthill will report on the results of a similar fresh approach to dyspareunia and frigidity

London S W 1

RONALD MAC KEITH

SIR —It was interesting to read Dr Tuthill's paper on impotence and few would disagree with some of his views It was rather surprising however that a psychiatrist should decry psychological methods of treatment and praise the use of male hormone for which he claims success Most endocrinologists would confirm the statement that testosterone is not helpful in cases of functional impotence and it has been my experience that common sense psychiatry is often adequate

If erectile capacity is not a constant but is reduced by stress, worry, or failure" why should small doses of exogenous testosterone increase it?

Erection is partly dependent on male hormone secretion from the testes but can occur without it For example a eunuchoid patient aged 34 with primary testicular agenesis and the penile development of a prepubertal boy was able to have intercourse regularly with his wife before he was developed maturely by testosterone therapy

An adult normal male whom I saw after his metamorphosis into a pseudo female had been treated with large doses of œstrogen for two years He told me that he was able to obtain rigid erection and his potency still persisted when his testicles were removed Even when a plastic surgeon had divided the corpora cavernosa, which were built into the form of labia, painful priapism necessitated their later amputation

Dr Tuthill's case records tell us nothing of the state of the gonads of his patients If these were normal, then presumably there was no reason why male hormone should not be secreted in adequate amounts

I hesitate to comment on the inefficacy of oral methyl testosterone therapy in such cases An implant of 100–200 mg testosterone in 25 mg tablets would possibly last some months with the daily absorption of a few milligrammes at first *In several cases of functional impotence with normal gonads,* judged clinically and by testicular biopsy, I have administered doses of 300 mg of testosterone phenylpropionate or testosterone isobutyrate twice weekly without any significant effect over periods of some weeks

Let us hope that the proprietary pill containing amphetamine *sulphate, strychnine, arsenic, and yohimbine is* categorised in group 6 of the Standing Joint Committee's classification of proprietary medicines I thought that yohimbine, like *cantharidin, was no longer fashionable as an aphrodisiac,* and in fact I have yet to hear of any drug which has been proved to have this power in the normally developed male

I feel that Dr Tuthill is too modest and that his records of successful hormone treatment of erectile impotence are really a tribute to his psychiatric technique and experience

Bristol G L FOSS

SIR,—Dr Tuthill's article is valuable for the encouragement it gives us to use simple adjustment, rational counsel, and physical therapy Yet as regards treatment it leaves us largely in the air Treatment seems to consist in advising the abandonment of restraint and prescribing endocrine therapy as a reinforcement One is reminded of the adage that cases of impotence are either very easy or very difficult to treat, and perhaps Dr Tuthill has not ony re discovered this fact, but has added to it counsel of value—namely, that we should adopt simple reassurance on rational lines before more disturbing techniques are considered Unfortunately he has too little to say about the difficult cases His comment on sex fantasies deserves consideration, and the whole paper is a worthy contribution to the literature on this subject The scorn with which he regards medical psychologists—men as sincere as he—is regrettable

## "TAKE A COUPLE OF FAT VIPERS"

SIR,—A critical mind was possessed by the anonymous author of the second edition of the *New Dispensatory,* published in London in 1746 In discussing the relative advantages of live and dried vipers in making vinum viperinum, he writes

> "Whether they communicate to the wine, either when used fresh or dry, so much virtue as they are supposed to do, is greatly to be doubted Some compositions under this name have been highly celebrated, as restoratives in debilities and decays of constitution, but what virtues of this kind they possessed, were supplied chiefly from other ingredients
>
> The viper is doubtless highly nutritious food, and in some kinds of weakness and emaciated habits, is not undeservedly looked upon as a good restorative To answer any valuable purpose, fresh vigorous vipers (not such as have been long kept alive after they are caught) should be liberally used as food the wines and tinctures from them can scarce be supposed to receive any considerable virtue from the animal, the dry flesh brought us from abroad is entirely insignificant'

This dispensatory describes the preparation of Theriaca Andromachi or Venice Treacle, one of the electuaries 'of wild exuberance of composition which the superstition of ages brought into vogue,' and lists 61 ingredients

It is interesting to learn from it that, while the College have somewhat facilitated the preparat medicines by omitting the hydeclroi and dried vipe College of Edinburgh, paying very little deference t or common prejudice, have ventured at length t these venerable reliques"

The Royal Hospital
Sheffield 1 PETER

## INTRAVENOUS HYDROCORTISON

SIR,—Hospitals holding stocks of corticotro cortisone have now received from the Ministr a small supply of hydrocortisone solution fo intravenous administration Until recently of this preparation has been available in th and few reports have been published about i May, 1953, the Medical Research Council made 1 2 g of an aqueous suspension of hydrocort alcohol (Merck), and after preparation by the described by Thorn et al [1] this was used infusion Certain practical details in the use venous hydrocortisone have been emphasised by experience and may be of value to others who able to use this new preparation

*Adrenal cortical Insufficiency*

In severe adrenal cortical insufficiency the firs treatment is to raise the level of circulating adren hormone If the patient is conscious and able to medication, cortisone tablets will produce a significa of the plasma 17 hydroxycorticosteroids in thirty minutes [2] If treatment by mouth is impossible, cortisone is of limited value because of its very slow rate Hitherto the only preparation capable of rapid increase of circulating hormone has bee cortical extract given intravenously Solutions cortisone are much more potent and likely adrenal cortical extracts for use in emergency

Severe adrenal cortical insufficiency requiring therapy may take the form of an addisonian cris develops gradually, depletion of sodium and fluid play an important part in the production of When treating a case of this type the concentrated hydrocortisone (100 mg in 20 ml 50% alcohol) added to 1 litre of physiological saline

On the other hand studies have shown that rapi ing adrenal insufficiency can quickly result in tension without any external loss of body practice this may arise in the course of adrenal patient with Addison's disease or cortisone-indu atrophy is subjected to a severe stress and possibly adrenal hæmorrhage In these cases there is depletion, and the hydrocortisone should be given glucose solution

Two cases of addisonian crisis have been tr intravenous hydrocortisone Both were of the slow ing type, one due to inadequate replacement th adrenalectomised hypertensive with impaired renal and the other in a previously undiagnosed case of disease The hydrocortisone had been prepared adrenal surgery and was therefore made up in isotc solution Furthermore, so that the clinical and b effects of the infusion could be studied, no other ster was given during the infusion or for some hours The results were disappointing, although there wa clinical improvement the effect soon disappeared patient with renal insufficiency the blood urea potassium levels rose Both patients responded to additional salt and oral and intramuscular

The poor response of these two patients may be to giving the hydrocortisone in isotonic glucose saline solution and to the fact that no additi therapy was given at the same time Hellman shown that hydrocortisone disappears from the very quickly after the completion of an infusion

---

1 Thorn G W Jenkins D, McCracken B H,
J A Reddy, W J *Trans Ass Amer Physns*
2 Nelson, D H Sandberg A A Palmer, J G,
*J clin Invest* 1952 31, 843
3 Pearson O H Hollander V P West, C D Whit
Randall H T *Ibid,* p 653
4 Hellman L Bradlow, H L Adesman J Fukush
Kulp J L Gallagher T F *Ibid,* 1954, 33, 11

xperience with these two patients we suggest that travenous hydrocortisone is used for the treatment of f addisonian crisis it should be given in isotonic saline and that injections of cortisone acetate should be ur hourly in the initial stages. Cortisone acetate by should be started as soon as possible Thorn et al [4] ggested that the intravenous hydrocortisone should at a rate of 25 mg per hour for the first two hours mg per hour subsequently; they also advise giving of deoxycortone intramuscularly in patients with a sma potassium level

patients developed acute adrenal insufficiency shortly eration. One patient had had a total adrenalectomy hing s syndrome; and although she had received of cortisone intramuscularly in the previous twenty urs, profound hypotension developed twelve hours eration An intravenous infusion of hydrocortisone in lucose solution at a rate of 12 5 mg per hour produ ediate and dramatic response The second patient cortisone therapy for two months before splenectomy dertaken for hæmolytic anæmia It was anticipated e patient s adrenals would be atrophic and unable to to the stress of surgery therefore 350 mg of intra r cortisone was given in the twenty four hours before ration. A further 150 mg was given in the next hours, but fourteen hours after operation there was fall of blood pressure Intravenous hydrocortisone in glucose was given Initially the rate was 6 mg per d the blood pressure moderately improved when the increased to 12 mg per hour it returned to normal.

*ative Shock*

et al [6] reported good results from intravenous hydro o given for the treatment of severe postoperative the absence of any evidence of adrenal insufficiency e two infusions to one patient in this condition but there was slight improvement it was not maintained patient ultimately died

is

se of intravenous hydrocortisone as a diagnostic test rentiating between tumour and hyperplasia in cases of s syndrome or adrenogenital syndrome was described r et al.[7] If effective it would have the advantage of uch quicker as a diagnostic procedure than the usual scular cortisone suppression test We obtained a ical result from this test in a case of Cushing s syn Although an infusion of 100 mg of hydrocortisone ver four hours failed to reduce the 17 ketosteroid no tumour was found at operation.

l account of these studies will be published in the sue of the *Archives of the Middlesex Hospital*

de of Clinical Research
Middlesex Hospital
London, W 1

JOHN NABARRO

## HEXAMETHONIUM AND THE PUPIL

—Several years ago while using hexamethonium e in the investigation of the vasomotor reactions ents suffering from poliomyelitis I noticed some ing changes in the pupillary reactions of these s. The changes included bilaterally equal mydri miosis, anisocoria isolated loss of the pupillary o light isolated diminution of the pupillary reflex ergence-accommodation and loss or diminution h the light and convergence accommodation

patients who received intramuscular injections of 40– of hexamethonium bromide 3 showed an isolated l loss of the light reflex 3 showed a sluggish con e-accommodation reflex while the light reflex remained nd 3 showed sluggishness of both reflexes 4 of the 9 had an equal mydriasis 3 had a marked anisocoria ad no change in pupil size

ould be interesting to know if there have been any l investigations of the effects of ganglion blocking agents on the pupillary reflexes—for example the injection of a blocking agent in graded doses into the internal carotid or ophthalmic arteries Such an investigation particularly by close arterial injection into the ciliary ganglion might throw some light on the mechanism of the Argyll Robertson pupil

Hoddesdon Herts

A McPHERSON

## SEX OF MEDIASTINAL TERATOMATA

SIR —Following on the recent observations on sexing by means of nuclear characteristics, and more particularly on the findings by Hunter and Lennox [1] in relation to the sexing of teratomata it was decided to ' skin sex ' our small collection of mediastinal teratomata The sections were reviewed and five cases selected in which reasonable areas of squamous-cell formations were found For controls skin biopsies were taken from six known males and six known females. The findings were as follows

| *Patient* | | *Teratoma* | |
|---|---|---|---|
| *Age at operation* | *Sex* | *" Skin sex "* | *Position* |
| 1 yr | M | F | Anterior |
| 18 yr | M | M | Posterior |
| 1 yr | M | M | Anterior |
| 7 days | F | F | Anterior |
| 24 yr | F | F | Thymic |

Having found one apparently contra sexed teratomata in the series I approached Dr Lennox, who kindly agreed to re-examine the material, provided that all indication of sex was withheld until his examinations were complete His findings fully confirmed mine and he was confident of the accuracy of the sexing in the case of the contra-sexed teratoma

The only comment I would make is in relation to the discussion in the paper by Hunter and Lennox [1] In males the proportion of XX, XY and YY zygotes should be 1 2 : 1 Clearly the heretical supermale YY is a potential novelty and the investigation of two questions may produce additional evidence : (1) does the proportion of female teratomata in males approach $^1/_4$ or $^1/_2$ as the statistical limit ? (2) is there a chromatin pattern characteristic of the (assumed) YY zygote ?

D BARRON CRUICKSHANK

## HARDENED FATS AND LUNG CANCER

SIR,—Professor Yudkin in his letter of Jan 1 claims that deficiency of essential fatty acids has never been shown definitely to occur in man But Burr [2] has referred to the study of eczematous patients in whom the blood level of both arachidonic and linoleic acid was lower than normal ; and he added Although the results with human subjects are not so uniform as those with experimental animals under controlled conditions it seems clear that many people are receiving less than their optimal requirement of linoleic acid. He also mentioned that an adult maintained for six months on a diet which produced deficiency symptoms in young rats felt no ill effect but he lost weight underwent a change in respiratory metabolism and suffered a marked drop in the arachidonic and linoleic acid content of the serum lipids

It is well known that hydrogenation of fats eliminates essential fatty acids and that the hardened fats so produced are used in margarine and other foods That does not mean that these foods are free from essential fatty acids but only that an increased consumption of these foods reduces the content of essential fatty acids in the diet Burr said :

> From a survey of the national dietary it has been estimated that linoleic acid constitutes 1% of the average American s food It is likely that many people consume less than this amount which has been suggested by some as the

amount required by rats It is not surprising, therefore, that there are individuals who, because of low intake or abnormally high requirement, respond to additional unsaturated fatty acids in their diet "

Lung cancer varies between town and country and from province to province, and so does diet A comparison only between whole countries, such as Professor Yudkin makes, cannot therefore tell us much The relatively low prevalence of lung cancer in females may be connected with the fact that female laboratory animals require less essential acids than males

Copenhagen JOHAN NYROP

## STRANGE LANGUAGES

SIR,—I feel somewhat diffident in replying to Dr Wayne's inquiry in your issue of Jan 1 , but may I point out that a *Polyglot Medical Questionnaire* in twelve languages was published by H K Lewis & Co two years ago? It depends, of course, what he means by " strange languages," but I think he might find this book helpful —especially if he is working in dockland It contains both popular and medical terms and the translations have been done by doctors who speak English as well as their own tongue

Droxford Hampshire S CHALMERS PARRY

## CHEMOTHERAPY OF LEPROSY

SIR,—Dr Jopling's letter (Jan 8), pointing out that results of sulphone treatment of leprosy in England are less favourable than I had found in Nigeria,[1] emphasises a point I myself made in the article in question I discussed the less favourable reports made also in the U S A , since no published reports were available for this country It appears possible that a racial factor influences the severity of leprosy and the results of treatment

As Dr Jopling surmises, I do not say that all is well with the treatment of leprosy , but I, and all other workers I know, do say that all is infinitely better than it was before sulphone treatment was introduced If I were completely satisfied with sulphone treatment, I should not have spent years on experimentation with the other chemotherapeutic agents mentioned in my article

I would discuss briefly three points

Firstly, in spite of what Dr Jopling writes, sulphone treatment of leprosy in England can give excellent results Although, through having been long abroad, my knowledge of leprosy patients in this country is very limited, I know of a few (though there must be more) English persons who, thanks to sulphone treatment, have fully recovered from lepromatous leprosy and are now living normal lives with no disabilities or deformities

Secondly, Dr Jopling's surmise that my patients in East Nigeria were easily cured because the disease had been rendered mild by the " clan segregation instituted some 20 or more years ago " does not bear examination When I arrived in Nigeria in December, 1947, I found in the Uzuakoli area about 12,000 patients under treatment and a degree of isolation at the Uzuakoli Settlement and its fifty outstations, under Dr T F Davey For our experiments with chemotherapy, to begin with we chose and treated in the one centre about 200 of the worst of these 12,000 cases, and particularly those which had become steadily worse despite many years of treatment with hydnocarpus oil With these patients we had many difficulties such as Dr Jopling describes and we described in previous articles , but in time the difficulties were overcome and cure was obtained, as recorded in my recent article During the next few years we gradually collected for special study another 900 highly active but newly diagnosed cases with no previous treatment, many of them from areas where there was no organised clan segregation In these cases the difficulties were very much less, and slow recovery is being seen in practically all of them

Finally, my experience is that with prompt diagnosis and early treatment, most of the complications mentioned by Dr Jopling do not often arise or are not serious I strongly suspect that in this country, for a variety of reasons, patients have not come under effective treatment soon enough to complications of treatment, which can be so which do subside in time We certainly found th Nigerian patients, with their early recognition of their determination to get better and to contin in spite of difficulties, we were fortunate in hav material to work with

It is possible, as I have already suggested, th factor helped us , but, even so, the results m such a large scale in a country where leprosy problem, do justify the opinion that a major in treatment has occurred , and I should li acknowledge our indebtedness to the workers nations—particularly German, French, and well as British—who contributed to this revolu

## SULPHONAMIDE SENSITIVITY OR DISSEMINATED LUPUS?

SIR,—Dr Fox rejected the diagnosis of dis lupus erythematosus, in the case which he re your issue of Jan 22, on the ground of a single marrow examination, done one month after th had lost her fever Had this examination been during the pyrexial period lupus erythemato still have been the most likely diagnosis The sex of the patient, the previous œdema of the onset in summer at the seaside, the malaise, p pyrexia, the morphology and distribution of the the rapid sedimentation rate, the loss of hair, tedious illness all point to disseminated lupus er tosus This is more than an academic point prognosis is serious

The sulphonamide may have activated the but it is not justifiable to regard this as a case sulphonamide sensitivity In disseminated lupus matosus a peculiar type of hypersensitivity for an unknown cause, spontaneously Attacks precipitated by exposure to sunlight or the ing sulphonamides

Edinburgh 12 ALAN L

## MASKED EPILEPSY

SIR,—Dr Kempton (Jan 22) tries to hoist my own petard He accuses me of ascribing every to one cause—epilepsy If he read my paper he would find that the 7 cases were drawn from 1400 patients and that I recommended a investigation to exclude other causes of the In the *British Medical Journal* of Jan 15 I h thirteen causes of abdominal pain in addition to lous mesenteric adenitis Dr Kempton prefer to the term "periodic syndrome," which he provisional He asks whether a diagnosis of is of benefit to anyone The answer is that later a child with periodic pain will become a unnecessary abdominal operation, as described in America More important is the fact that one of the patients will have a severe and attack from which he will not recover Such a reported by Brown[1] If we can prevent only these tragedies then it is worth all the "d social implications" of revealing the true the parents In my experience parents are sensible and only too pleased to have a rationale tion of a disease which has obviously puzzled their advisers They are even more grateful it cured

Dr Scott asks about toxic effects of pheno In case 7 the drug reduced the incidence of but made it more severe when it did occur Th what happens with grand mal sometimes I noticed any behaviour disorders or irritability cases these complaints were relieved by pheno e.

## TUMOURS OF THE GLOMUS JUGULARE

SIR —An interesting point arises from Dr Holesh s paper of Jan 22 Cell nests resembling the glomus caroticum, are found not only at the bifurcation of the common carotid artery but also in the adventitia of the ascending aorta its arch or in the innominate artery in the ganglion nodosum of the vagus nerve in the adventitia of the jugular bulb or along the course of the tympanic nerve (glomus jugulare) and in chimpanzees they have been discovered in the orbit in relation to the ciliary ganglion[1] Tumours arising from each of these sites have now been described[2]—excepting the orbit One of our series of patients with glomus jugulare tumours[3] had a very marked proptosis and at necropsy the tumour was seen to lie in the orbit but it appeared to have invaded it by extension forwards from the petrous area rather than to have originated there.

Dr Holesh s case 4 however also showed a proptosis, but some years before any of the other signs developed and in view of the well known tendency for the glomus tumours to form concurrently in two or more sites, it seems worth considering the possibility that the original site of tumour formation in this case might have been the orbit and that this type of tumour might be included in the differential diagnosis of causes of unilateral exophthalmos

Another feature in the diagnosis of these tumours is their tendency to present as a tongue of tumour inside the lumen of the jugular vein and to be found as a pulsating swelling having a palpable thrill and audible bruit under the lobe of the ear between the mastoid and the jaw This was most marked in 1 of our series[3] and in 2 of the cases of Henson et al[4] and it has occurred in just under 10% of all reported cases

established by the University of Manchester in this department in 1934 This research unit appears to have been the first of its kind, and the procedures that my wife and I have evolved for testing the hearing of children aged 3 months to 5 years have been reported in the *Journal of Laryngology and Otology* and in our books

In a recent report on *The Health of the School Child* the chief medical officer of the Ministry of Education has been good enough to refer in some detail, and very favourably, to my wife's work in training health visitors to test the hearing of children at maternity and child welfare clinics, under the supervision of medical officers My wife has found health visitors to be very suitable for this work In the cities of Birmingham, Leicester, and Salford, and in Lancashire, Leicestershire, and Northamptonshire, screening tests have already been begun of the hearing of all children who are brought to maternity and child-welfare clinics With my wife's help a growing number of health authorities are establishing guidance clinics for the parents of children who have been found to be handicapped by deafness (which is not amenable to medical or surgical treatment) and who have not started school

A collaborative project, for the further study of deafness in childhood, in which senior members of the staffs of the departments of otolaryngology and education of the deaf, in this university, are taking part, is at present in progress

## ARTIFICIAL HIBERNATION IN POLIOMYELITIS

SIR,—In your issue of Jan 15 Dr Brehme states that in bulbar respiratory paralysis chlorpromazine would, by lowering the basal metabolic rate, decrease oxygen consumption and so lessen the risk of anoxæmia Although it was at first thought that chlorpromazine decreased oxygen consumption, later work has in fact shown that this drug slightly increases oxygen consumption For this reason, and to avoid the tachycardia which chlorpromazine produces, I have used 'Hydergine' (which contains the methanesulphonates of the three alkaloids dihydroergocornine, dihydroergocrystine, and dihydroergokryptine in equal proportions) in lieu of the chlorpromazine constituent in the lytic cocktail Like chlorpromazine, however, hydergine can produce profound hypotension when given intravenously

W N, ROLLASON

## NOTES ON TRANSFUSION

SIR,—"Clinical Pathologist" (Jan 22) is to be sympathised with in his concern to prevent the wasting of blood that has been cross-matched but then not required, and a more realistic approach to the problem by the Ministry is desired

In the first place, pathologists and technicians worth the names are capable of breaching sterile containers without admitting infection—that simple procedure is part of their training, and without it no culture of any sort could be put up in the bacteriology department

In the second place, it is urged that those of us who cross-match blood should stain a film of a sample of each bottle by Gram's method as part of the essential technique This at once removes any value of a pilot tube as only the blood in the pint bottle matters in the examination for organisms Thus the bottle must be breached Why then go to the expense of fitting pilot tubes ?

Either a pilot tube to prevent repeated bottle punctures or the staining of a film for bacteria is desirable Both together are incongruous—and incongruity is what we try to avoid in cross-matching blood !

[illegible] Hospital

C A K BIRD

SIR,—Reading through the correspondence columns, an onlooker must come to the con does Clinical Pathologist in his letter last several important problems would be solved universal introduction of pilot tubes

I have been *expecting to see an* putting forward the objections to pilot tubes been said that pilot tubes are objectionable the danger of switching these tubes either at the session or subsequently, and also because the inside the main bottle may be infected or dam the pilot-tube blood remains unchanged The the blood in the main bottle was dangerous go undetected at the time of cross match Th would seem to be small, and it would be helpful if we could learn whether the experts that such risks can reasonably be disregarded.

ANOTHER CLINICAL PA

## WATER DIURESIS IN PRIMARY M

SIR,—Both the recent article by Dr Hubble and the letter from Dr Fraser and Dr Garrod that failure of water diuresis is not uncommon myxœdema

Hubble cites Crispell et al [2] as supporting this et al believe that there is failure of water diures myxœdema , but detailed analysis shows that, of their patients had a poor diuresis compared people, only 3 cases of the 11 had a failure of of the kind seen in adrenal deficiency Garrod and found that in 16 out of 18 patients with the rate of urine flow and the proportion of excreted were very different from the results in patients with hypopituitarism Levy et al [4] found water diuresis in all 3 cases of primary myxœdema studied.

RESULTS OF WATER DIURESIS TEST (1 LITRE INGESTED) IN 9 CASES OF PRIMARY

| Case no | Sex | Ætiology | Max rate of urine flow (ml per min ) | Proportion of load excreted |
|---|---|---|---|---|
| 22 | M | Idiopathic | 6 8 | 100 % in 3½ hr |
| 26 | M | Surgical | 8 4 | 80 % in 3½ hr |
| 30 | F | Surgery and X ray | 6 0 | 66 % in 4 hr |
| 38 | F | Surgical | 11 0 | 94 % in 4 hr |
| 39 | M | Idiopathic | 3 3 | 55 % in 3½ hr |
| *40 | F | Idiopathic | 6 3 | 84 % in 3½ hr |
| 41 | F | Idiopathic | 6 0 | 65 % in 4 hr |
| 42 | F | Idiopathic | 7 0 | 100 % in 4 hr |
| 43 | F | Idiopathic | 2 5 | 33 % in 3½ hr |

* This patient had thyroid extract gr 1 per day for the test

The accompanying table shows the results of diuresis tests in 9 cases of primary myxœd technique used, and the results in cases 22 and already been reported [5] In 7 out of the 9 cases diuresis was normal In 1 (case 39) of the there was concomitant heart-failure, and, known, patients with heart failure due to have a failure of water diuresis

I still believe that the water-diuresis test valuable in distinguishing primary myxœd myxœdema secondary to hypopituitarism patients with primary myxœdema have a water diuresis of the kind seen in hypop and in this event cortisone will not produce

## CANCER OF THE LARYNX

I was interested to read Dr Maxwell's article x on the incidence of cancer of the larynx in o the incidence of cancer of the bronchi

ve he has made a fundamental error in drawing lusion that it is now certain that cancer of ax has not increased in frequency during the iod in which cancer of the bronchi and lungs me very much more common His conclusion on the Registrar General's figures for deaths se diseases over a period of years

of the larynx is a superficial form of cancer or the fact that it reacts favourably to adequate t—surgery or irradiation or a combination of very experienced laryngologist has cases which n followed up for many years and in which no recurrence though the patient may die of er disease On the other hand cancer of the eneral does not respond to treatment which is arely palliative

egistrar General's figures for deaths from cancer ing accurately reflect its incidence but the r deaths from cancer of the larynx relate only to or untreated case or the case that has not d to treatment and they do not, in my opinion ue picture of the extent of cancer of the larynx his disease is probably also on the increase

Doncaster

PHILIP H BEALES

## INSECTICIDAL LACQUER

In your annotation of Oct 9 you estimated that cost £50 to apply insecticidal lacquer to a kitchen and £5 to treat a ward kitchen You aid that 'the lacquer has to be applied by and the cost is high though perhaps not in view of the long term benefit.

gard all these statements as incorrect. In the the cost should not be nearly as high as stated lthough of course the actual cost will vary to the size of the kitchen Secondly insecticidal suitable for use by any energetic person One ntains sufficient to treat *80–100 square yards* not necessary to treat the whole surface but int strips, 4–6 inches wide along edges crevices t haunts.

employment of a technical disinfestation service l committee make use of expert knowledge and e as well as qualified operators and for this e to pay In many cases it may be decided is well worth the extra expense involved. None we feel that your annotation presented a false your readers since where the hospital decides the material with its own personnel it should be ut those costs by at least 50% Under these nces we have no doubt that the use of insecticidal will be a more attractive proposition to your

METALLURGICAL CHEMISTS LIMITED

Broad Street
on, E.C.2

r estimate for treating a hospital kitchen was from a servicing company and we understand director of the company had in mind a very large kitchen In such jobs as in the building industry generally the cost of skilled labour is often much greater than that of the materials themselves. Our opinion that insecticidal lacquer should be applied by experts was based first on the need to mix it immediately before use with an accelerator containing 10% sulphuric acid and secondly on the precautions that have to be taken during application (For example in telling people how to use their product Kyplaq our correspondents say Do not inhale vapours Ensure maximum ventilation Do not expose naked lights during application or for 3 hrs afterwards Wash hands and face with soap and water after applying Do not overpaint or the actions of the insecticides will be impeded ) Thirdly the best results will be obtained by someone who knows the haunts of the insects and what kinds of surface are most suitable for treatment —ED L

## TOO MANY ANTIPYRETICS?

SIR,—At a time of the year when influenza and acute coryza are all too common it is pertinent I think to inquire again on what grounds the very widespread use of antipyretics is based

Not only do the public flock to buy many millions of bottles of tablets of various mixtures containing salicylates but the main aim of many practitioners appears to be to promote diaphoresis and to lower that raised body temperature at all costs—in other words to get their patients to sweat it out Of course most of these mixtures and the time honoured Dover's powder are analgesics but it is the antipyretic side of their action which I maintain is irrational

On more than one occasion I have allowed my own pyrexia to deal with the invading pathogens and it has coped pretty well. I do indeed endorse the statement[1] that the reduction of temperature is rarely indicated '

London S E 9

N P BRONSDON

## ISOBEL CRIPPS CENTRE

Dr B Courtenay Mayers writes

May I as medical adviser to this centre, correct the unfortunate impression given by Dr Barlow (Jan 15)? Every *possible safeguard is being taken by Mr Neil and his colleagues.* I myself have seen many of Mr Neil's pupils, who have not been under other medical care and I know that other doctors have too I have every confidence in Mr Neil's work and provided suitable cases are chosen—i e cases where poor posture malcoördinated movement or undue tension play a significant part—then very good results can be obtained I am surprised that Dr Barlow should confuse Mr Neil's case with that of the osteopaths: to do so is to say the least of it, highly misleading

Dr Wilfred Barlow writes

For several years Mr Neil has carried out an intensive advertising campaign in the national press In several of these advertisements he cites medical conditions—e g., A method of proved value in many states of physical ill health and psychological disorder One advertisement tells people to *Ask Your Doctor about his school* and this to the layman might easily imply general medical support It seems to me meaningless to talk about being ethical after one has advertised in this way however zealous one may then be in contacting the doctors whose patients have come as a result of the advertising The fact that Mr Neil has his own medical adviser to whom he refers those who are ill or suspected of illness still leaves the onus of suspecting or "not suspecting" on him.

There is nothing to prevent individual doctors from investigating a heterodoxy but if general medical coöperation is sought for it I still think that it would be wiser to insist on the safeguards which are given say by physiotherapists who do not advertise

# Obituary

## HAROLD KIRK WALLER

M B Camb , F R C O G

Dr Harold Waller possessed in full measure the qualities that become a doctor Courteous, gentle, witty, and humble, he had a scholar's wide culture and persistently inquiring mind , and he was a trusted friend to many In particular his perceptive understanding of women was the basis of his special contributions to medicine—his work for the better training of health visitors and midwives and for the education of mothers, and his detailed studies of the processes of breast-feeding He could not have achieved so much without a constancy of purpose amounting to a vocation, yet he never allowed this to obtrude His enthusiasm was tireless, but his persuasion rested on no stronger phrases than a quiet " I think it so important "

[Elliott & Fry

He was born in 1881, the youngest but one in a family of sisters His father, the Rev Horace Waller, had worked in Central Africa with David Livingstone, shared in the anti-slavery movement, and was an intimate friend of General Gordon he died when his son was 15 He was educated at Charterhouse School, Trinity College, Cambridge, and University College Hospital, London On qualifying in 1909 he became house-physician to John Rose Bradford and Batty Shaw Later, while serving as R M O at Queen Charlotte's Hospital, he started with a colleague the first child-welfare clinic In 1911 he was appointed R.M O at the East London Hospital for Children, Shadwell, where he worked under Eustace Smith, J A. Coutts, Morley Fletcher, and also Wilfred Trotter to whose influence he often paid tribute

During his time at Shadwell an epidemic of gastroenteritis overwhelmed the hospital There were more than 3000 cases some cots were even occupied by three dying babies within a day The most up-to-date treatment then consisted in little more than trying to maintain fluids by subcutaneous injections of saline, and a baby's chance of survival depended mostly on successful breast-feeding and on the mother's knowledge of hygiene After that saddening experience, whatever his other activities, Waller's first concern was always the technical details which make breast-feeding possible, and the spread of knowledge about child care

In 1912 he settled in Chelsea, and his large practice was soon chiefly among mothers and children But he also found time to acquire experience of infant welfare under Eric Pritchard who was already urging the need for preventive work among the poorer mothers When, in 1914, the Royal College of St Katharine, in Poplar, became a training-school for the first health visitors and a welfare centre equipped with clinics and a few beds, Waller was appointed superintendent medical officer Except for his war service with an ambulance unit, he remained on the staff until 1948 There he taught the health visitors and with others started antenatal clinics, the first dental clinics for children, facilities for tonsillectomy, and a ward for infants who were not thriving A garden for sunlight treatment and an artificial-sunlight clinic for the treatment of rickets were added in 1921

In 1912 he heard of the work of Mrs Lelia Parnell, Miss Alice Gregory, and Miss Maud Cashmore, who founded the British Hospital for Mothers and Babies at Woolwich Their ideals of better training for midwives and better supervision of the expectant mother appealed to him and he joined them as physician and lecturer to the nurses. Thus began an association which lasted until his death Through it the small unknown hospital in a poor inaccessible district won a reputation throughout the world for the excellence of its care, the training of its midwives, and the original investigat out

For many years his work was thus divided Poplar, Woolwich, and Chelsea where his included many confinements He was a hi obstetrician and has been called the " first of th practitioner obstetricians " In 1927 when Babies' Club was formed he became its me and from his skill and gentle wisdom has com its success But his interest was more and more to child welfare and he gave up his practice in more of his time to research on breast feeding end he received a grant from the Goldsmith's

At Woolwich Waller was able to test his management in breast-feeding He had al to the conclusion that the natural process, if le failed about a third of the babies as a sourc The failure was commonly attributed to the ness of the baby's suction But he questioned we are always right to place on the child th onus of withdrawing the milk " He noticed failure of secretion followed engorgement and prevent it by antenatal expression of viscous postnatal expression to avoid overfilling, the tration of stilbœstrol to reduce tension within and the use of a simple appliance to improve of poorly formed breasts and nipples He importance of the baby's position at the the unending vigilance needed to combat sore nipples He was the first doctor to describe th reflex and to draw attention to its importan difficult, now that his methods have becom established and much of his work is common to appreciate the wealth of patient original observation on which it rested His book, C *in Lactation*, when it was published in 1037, have no word in common with previous to women who had fed their babies from th rang with truth

Most of his work related to breast-feeding, For instance, in the '20s while working at Popl to sit about in dockers' homes to see what had to eat, because dockers were so power He found that their diet included steak, tripe, trotters and he came to recommend a liberal protein diet for weanlings far in advance of th of the time He always kept in touch with background of his patients, and during the b used to visit old people in their shelters and Poplar during the bombing to persuade evacuated During raids on Woolwich he the midwives on their visits to allay fear

He was fortunate in being able to convey his not only in scientific journals and books, b talks, for he was a gifted teacher He had speaking and writing which lightly and easily attention He taught by relating examples memorable because of their humanity The emotions were gripped and yet there was slightest trace of sentimentality an emotional to breast-feeding, so easily assumed, embarr He was among the first to see the possibilities casting as a means of educating mothers in c and he availed himself of it from the early broadcasts were so vivid that many of his listen feeling that he held a real baby in his arms as h

In the past decade his views had won wide He was invited to lecture in America and Ne but ill health prevented his accepting He was able to go to Paris to address an international in 1953 The same year he was elected F.R also received the Dawson Williams prize On ment a fund was raised, primarily by the British Hospital for Mothers and Babies, to tribute to him, bed sitting-rooms for the mothers and babies Though the building complete he saw it begun and took delight in its progress He died at Wadhurst on Jan 1

A G H writes

" I met Harold Waller for the first time at 1911, the year of the great epidemic of gastro-enter the summer and autumn 3118 cases were trea hospital The appalling mortality affected him eve determined him to devote the greater part of onal life to the care of children Time meant little en he was dealing with anxious cases and it was him that he would often awake to the fact that he late at the clinic and that there were appointments m busy in his general practice until midnight or had built an extensive general practice but this tirely satisfy him for his heart was in the problems welfare to which he gave all his energy when he his private work in 1933

the past fifteen years his health was a constant but he never complained and refused to let it is work. His keenness was infectious and he was colleagues and patients His characteristics were kindness, humility and a great capacity for —a handsome gentleman in every sense of the

r old friend F C N describes him as a man gh he held strong views never pushed them

s glad to see others researching along the same nself and never assumed the title of leader although was this to many of us Though he was reserved and eared distant he was not pompous he had an knack of being able to laugh at himself Quite wrote to a friend who had been ill and said Adopt le of the oriental and sit contemplating nothing d this is impossible but in old age it is so seductive en for dignity

## JOHN DUNCAN WHITE

M.B Edin, D.M R.E

ncan White, who retired last year from his ent as radiologist to Hammersmith Hospital r lecturer in radiology at the Postgraduate School of London died on Jan 21 after a s largely due to his work. He was 59 years

duated M.B in the University of Edinburgh d held house-appointments at Edinburgh Royal and the Mansfield and District Hospital On n to civilian practice after service with the he decided to specialise in radiology and he D.M.R.E. in 1921 He was for a time an assistant t at St. George's Hospital London he was l to the staff of St Giles Hospital and of the of St. John and St. Elizabeth in 1924 and of ital for Tropical Diseases in 1927; and in the he also joined the teaching staff of the British of Radiology In 1930 he returned to Edinburgh r of the department of radiology at the Royal ; but after four years there he was chosen to t director of the department of radiodiagnosis ersmith Hospital joining the Postgraduate chool of London as lecturer in radiology He me senior adviser in radiology to the London ouncil a post which he held until the start of nal Health Service in 1948 He continued to Institute of Radiology as a member of its nd in 1935 he was its president. His enthusiasm aching of radiographic techniques had early him into contact with the Society of Radio- and his critical and constructive interest in ty's activities was maintained after his return n.

he was released from his duties at Hammer- spital to take charge of the training of personnel miniature radiography in the Army In 1953 appointed O.B.E. and the following year he

rsonal tribute J F B writes:

h Duncan White taught and showed the highest of radiology to his students radiographers and he did not consider the production of a spectacular his goal but merely a means to help the patient ity enthusiasm, and desire to render to his patients t service radiology could give unfortunately resulted radiation burns which necessitated several amputa hese ominous signs, though associated with much borne silently with great fortitude

R E S writes:

Dr Duncan White was a man of infinite courage—both physical and moral. His encouragement and support can only be appreciated by those who were closely associated with him He was a man of varied interests with a phenomenal memory for detail in connection with his work, a charming host and a most amusing conversationalist—qualities which were greatly appreciated by his many friends. Not only in England but also in the Dominions there are many radiologists holding posts of responsibility who owe a great deal to his foresight and teaching

In his marriage to Mrs. Clare Wigfull eighteen months ago he found great happiness and she proved a constant and devoted companion to him during his long illness

## JAMES BLAKELY MILLER

M.D LL.D Glasg D.P H J.P

Dr J B Miller who died on Jan 14 at the age of 77 was chairman of the Representative Body of the British Medical Association from 1946 to 1948 His years of office were arduous and eventful. They covered the passage through Parliament of the National Health Service Act and the long negotiations between the Ministry of Health and the medical profession before the service was set up The seven meetings of represen tatives over which he presided during these critical times gave full scope to his skill as a chairman

He was born at Kirkintilloch Dunbartonshire the son of the Rev Andrew Miller He was educated at Glasgow High School and Glasgow University where he graduated M B with commendation in 1898 After serving as senior assistant at Town's Hospital Glasgow he settled in general practice at Bishopbriggs a mining and agricul tural town near Glasgow In 1905 he became M D, again with commendation He was also M O.H for the neigh bouring burghs of Kirkintilloch and Kilsyth and in 1909 he took the D.P.H As a citizen, as well as a doctor, he took a full part in the life of the community and his many honorary appointments ranged from justice of the peace for Lanarkshire to the trusteeship of the Cadder and District Miners and Community Welfare Since 1922 he had been actively associated with the work of the B M A. and in 1929 he was elected to the council Since then he has served on many of the Association's committees, notably those concerned with public health industrial medicine and medical planning In 1951 he was elected a vice-president of the Association

When, in 1951, he completed fifty years practice his friends and patients made a public presentation to him. Last year when the B M.A met in Glasgow the honorary degree of LL.D was conferred on him by the university in recognition of his mastery of the difficult [illegible] of general practice

A T R recalls that none of the seven Representative Meetings over which Miller presided was an easy one.

With the National Health Service [illegible] repre sentatives came eager to add the [illegible] of their divisions to the doubts and discontents of the day Miller's experienced chairmanship his sense of the meeting and his patience and never failing humour [illegible] and the Representative Body in good stead. [illegible] giving every speaker his due hearing [illegible] for the moment when debate could give place [illegible] the meetings calmly and [illegible] Representative Body were his friends [illegible] when his chairmanship [illegible] ended and it was a real [illegible] Glasgow meeting last year. [illegible] was as alert and witty as [illegible] pleasure from meeting [illegible] the graduation when [illegible] degree he was aptly [illegible] those virtues which [illegible] revered figure [illegible] revered and loved [illegible] him.

Dr Miller married [illegible] the Rev J B A [illegible] and two [illegible] Miller [illegible]

## CECIL GORDON ROBERTS

B A, M D Camb

Dr C G Roberts, deputy Treasury medical adviser, died on Sept 8, at the age of 48, at Tamworth in Australia while on holiday with his wife

He was educated at Uppingham and at Emmanuel College, Cambridge In 1927 he took the natural sciences tripos, part II, in physiology, a training which later coloured his approach to the problems in industrial medicine He continued his medical studies at the Westminster Hospital. He qualified in 1930 and after holding house-appointments he became resident medical officer at the Westminster Later he was for a time resident physician at Ruthin Castle

In 1934 he joined the medical staff of the General Post Office under Sir Henry Bashford, who was then chief medical officer During the war years his clinical ability, cheerfulness, and optimism did much to maintain the morale of the staff at headquarters, who were then entitled to medical attention under the old Post Office medical service He trained many hundreds in first-aid and he was unstinting in giving of his time to the many charitable and social activities of the Post Office He interpreted the responsibilities of medicine widely, and he had *remarkable success in getting the idea across that* medicine was concerned with every aspect of the well-being of the workers in industry In 1943 he was promoted second medical officer and two years later chief medical officer When the Government medical services were reorganised in 1948 he became deputy Treasury medical adviser His influence during this difficult transitional period was great, and to a large extent the smoothness of this transfer was cooperation

About a year ago he decided to emigrate He was attracted by the scope of industrial there and he wished to give his two sons in a new country During his last few Treasury he initiated many changes, and he by many doctors on industrial medical of them, J N M., writes

"When the Social Medicine Research Unit years ago to set up epidemiological studies on disease, Roberts was one of the first to whom advice and help He was immediately *and thereafter, until he left for Australia*, we the experience of postmen and other grades organisation he served He was a delightful with—warm, enthusiastic, and full of ideas. unusual breadth of interest, and a rich fund of the people for whom he was caring At the was actively concerned with mass statistics and of large scale administration His physiological him insight into the "human engineering" job, his psychological interests led to useful both theoretical and practical, on health and relation to the size of working groups He *great clarity on topical questions of industrial* political developments that came from the Service and the growing concern of trade unions matters, and, particularly, about current human side of industry, in welfare, personnel the human relations' movement At a time medicine is having difficulty in finding its order of things his counsel will be sorely missed"

## Diary of the Week

JAN 30 TO FEB 5

### Tuesday, 1st

British Postgraduate Medical Federation
5 30 P M (London School of Hygiene and Tropical Medicine, Keppel Street W C 1) Dr E F Gale Actions of Antibiotics on Bacteria

St Mary's Hospital Medical School, Paddington W 2
5 P.M Mr Aleck Bourne Functional Uterine Hæmorrhage

### Wednesday, 2nd

Institute of Laryngology and Otology, 330, Gray's Inn Road, W C 1
6 P M. Prof M. Arslan (Padua) Effects of Ultrasonic Waves on the Ear

Institute of Dermatology, St John's Hospital Lisle Street, W C 2
5 30 P.M Dr J O Oliver Bacteriology of Skin Diseases

Institute of Diseases of the Chest, Brompton S W 3

# Notes and News

## WORLD HEALTH ORGANISATION

eenth session of the Executive Board of W H O Geneva on Jan. 18 under the chairmanship of van Zile Hyde (U.S.A.) It was announced that t few months the Organisation had set up a net poliomyelitis research laboratories which would extended These laboratories would study and ocal strains of the viruses of poliomyelitis and of eases—in particular those of encephalomyelitis rd adopted a resolution to give first priority in the ublic health to the promotion of research into the radioactivity Dr M G Candau director general said that early planning was needed if the dangers n the increasing application of atomic energy to were to be avoided The W.H O programme was to include the collection and dissemination of on on the medical and biological aspects of atomic d the training of personnel in methods of protection

## SCHEME FOR JUNIOR HOSPITAL STAFF

xford Regional Hospital Board is introducing into s hospitals a scheme designed to meet the needs of ctors who on completion of their National Service extend their experience before entering general r being selected for training as specialists. Many young doctors are married and find themselves r financial and other reasons to take up short ts in the hospital service

eme provides for the creation of a limited number of intern posts in the salary grade of junior hospital fficer (£775 × £50 to £1075) to take the place of osts on the junior hospital staff They will be tenable ars and will be held in the Reading and Northampton f hospitals (four posts in each group) Every effort ade to provide accommodation for married doctors r the hospitals at an economical charge

s of these posts will be expected to serve for approxi months in each of the major departments of the medicine surgery pædiatrics and obstetrics) and to the other departments as circumstances in the day nning of the hospitals may require

ought likely that most of those holding these posts more years will elect to enter general practice and nority will wish to train as specialists in branches of to which they are specially attracted or for which e a special aptitude The latter (if selected by their t) will have the opportunity to take up posts in the departments of their own or other hospitals in the taining the salary increments in their grade

egional committee of the executive councils has l its interest in this project and willingness to in facilitating the entry into general practice of rained under the scheme

## LOIASIS

eeting of the Royal Society of Tropical Medicine and in London on Jan 20 members of the staff of the l School of Tropical Medicine and their colleagues under the Colonial Medical Research Committee l researches on loiasis in the British Cameroons.

R. M Gordon showed that various species of chrysops en confirmed as actual or potential vectors that l infected from man can transmit the infection to monkeys that the *infection is widespread in the* on of many rural areas of West Africa though the l incidence is often less than would be expected from of the biting habits and the infection rates of the and that as yet we do not know enough of the history of this disease and particularly of the extent ortance of monkey reservoirs, to institute large and e schemes of control

ast point is implicit in the study of chrysops species tribution and breeding reported by Mr W Crewe H Oldroyd *C silacea* is the vector par excellence umba area because its behaviour allows the requisite with man Chrysops seems to be a genus of savannah d from which a few species have migrated to the ing Dr B O L Duke has observed that *C silacea* cted to wood smoke; it bites through most of the hours and therefore has a maximal chance of picking up the microfilariæ of *Loa loa* which shows the well known diurnal periodicity of this species But loiasis in mandrills infected with adult *L loa* taken from a naturally infected mandrill showed nocturnal periodicity; so far no essential difference has been found between human and monkey strains.

Prof J J C Buckley discussed the general features of development and ecdysis of microfilariæ in insect hosts and Dr Frank Hawking filarial periodicity He has in previous work shown that periodic microfilariæ seek the capillaries of the lungs at certain hours of the day this probably being the optimum site for them.

Dr W E Kershaw has studied the epidemiology of this infection in the rain forest its abrupt fringe the mountain grassland and coastal areas taking into consideration the population and its distribution in urban and plantation areas His empirical approach to these problems was supplemented by an analytical approach of great interest in which a mathematical model was constructed on the basis of the factors involved

In the discussion Sir George McRobert referred to the psychological effect of this infection in European residents of the endemic area and to the fact that the pathological effects of these migratory adult worms are little understood Prof A W Woodruff spoke of the importance of exact diagnosis since the value of diethylcarbamazine can be seriously underrated if wrongly given in non specific allergic states. Apart from the finding of microfilariæ (in which recent concentration techniques are valuable) eosinophilia, the complement fixation test and a recent history of Calabar swellings are important pointers. Diethylcarbamazine can eradicate even long standing infections.

## RESEARCH IN CEREBRAL PALSY

The Nuffield Foundation is financing a five year programme of research at Frenchay Hospital Bristol into the neuropathology of cerebral palsy and mental defect This grant will enlarge the scope of the work already being carried out by the Burden Mental Research Department of the South Western Regional Hospital Board The Burden Research Committee under the chairmanship of Dr J G Greenfield has been responsible for long term investigations into mental deficiency and the neuropathological side of these researches has been under the direction of Dr R M Norman, lecturer in neuropathology at the University of Bristol who has recently been given a full time research appointment by the board

A new laboratory is now being equipped and Dr H Urich, a lecturer in the department of pathology of the university has been appointed to assist Dr Norman The work will be undertaken in coöperation with the departments of pathology and child health of the university Its main purpose is to examine the brains of patients who have suffered from cerebral palsy and whose early history and clinical condition have been adequately recorded There are at present few detailed studies of both clinical and pathological data and for this reason much uncertainty exists as to the part played by birth injury in the pathogenesis of cerebral palsy

The new research team will have access as in the past to cases from the local hospitals but it is hoped that when the new laboratory is in operation clinicians and pathologists from other regions who have suitable material will use the facilities at Frenchay for the detailed examination of the nervous system.

## BACTERIA IN INDUSTRY

Even among culture collections there is increasing specialisation and several new ones were created in 1950 on the decentralisation of the Medical Research Council's National Collection of Type Cultures One of these the National Collection of Industrial Bacteria has just published a catalogue[1] of bacteria primarily of interest to industrialists but this catalogue also contains two lists of wider interest The first is a list of compounds produced by different micro organisms maintained in the Collection—e.g., acetone is produced by three strains of *Clostridium acetobutylicum* and penicillinase by two strains of *Bacillus licheniformis* and by one of *B subtilis* The second is a list of strains used for microbiological assays; folic acid can be assayed either by *Lactobacillus casei* NCIB 6010 or by *Streptococcus fæcalis* NCIB 8123

## THE ELDERLY WORKER

In his third report[1] on the later working life in the building industry (part of the Nuffield Foundation's inquiry into the needs of old people), Mr F Le Gros Clark assesses the extent to which special use is made of older employees Most firms which he questioned agreed that older workers should relinquish constructional work for less arduous duties of maintenance and repair Few favoured grouping elderly employees in separate gangs, since young workers learn much from their older colleagues, who in turn obtain considerable assistance from their stronger and more agile juniors Mr Le Gros Clark concludes that the building industry will be able to employ an increasing proportion of elderly craftsmen, provided always that careful attention is paid to finding them work of a suitable nature

### University of London

Dr Otto Klineberg, of the Department of Social Sciences, UNESCO, and professor of psychology at Columbia University, is to deliver two lectures, on Feb 14 and 15 The first is entitled Psychology and International Relations, and the second Uses and Limitations of the Experimental Method in Social Psychology Both lectures will be given at 5 30 P M, at the Senate House, W C 1

### University of Birmingham

Dr W Mayer Gross, part-time consultant psychiatrist at Uffculme Hospital, has been appointed senior fellow in the department of experimental psychiatry Dr Mayer Gross was formerly director of clinical research and consultant psychiatrist at Crichton Royal Mental Hospital, Dumfries Dr K H Ginzel has been appointed senior research fellow in neuropharmacology, and Dr P B Bradley lecturer in electrophysiology, in the department Dr J Williams has been appointed lecturer in anatomy

### Royal College of Physicians of London

On Tuesday and Thursday, Feb 8 and 10, Dr J A Smiley will deliver the Milroy lectures, on Personal Factors in Accident Proneness Both lectures will be given at the College, Pall Mall East, S W 1, at 5 P M

### Society of Apothecaries of London

At recent examinations the following were successful

*M M.S A* —A P Camilleri, S Miller
*L M S S.A* —R N Wade, P M Gurring, P Jago F R. F Dibb T Freuchen, A P Brown, E A Capell, D A Bennett, J E Todd J A. Bradford
*D.I H*—Z Khan, W H Suffield

### North of England Obstetrical and Gynæcological Society

The following officers have been elected for this society for 1955

President, Mr H J Malkin hon treasurer Mr C H Walsh hon general secretary Mr J B Cochrane, hon reporting secretary Miss U M Lister

### British Association of Plastic Surgeons

The following officers and council have been elected for 1955

President Prof T Pomfret Kilner, hon treasurer, Mr R. P Osborne, hon secretary, Mr J P Reidy council, Mr J N Barron Mr W Hynes Mr P H Jayes, Mr D N Matthews, Mr Rainsford Mowlem Mr Mortimer Shaw, Mr J S Tough, Mr A B Wallace

### College of General Practitioners in Scotland

The Scottish council of the college was constituted at a meeting held in Edinburgh on Jan 13 Dr J M Henderson (Pitlochry) was appointed chairman, Dr Lowell Lamont (Edinburgh), vice chairman, and Dr Richard Scott (Edinburgh) hon secretary and treasurer Other members of the Council are

D Peebles Brown (Kilmalcolm) Mary Esslemont (Aberdeen) C M Fleming (Edinburgh) W W Fulton (Glasgow) W S Gardner (Glasgow) I D Grant (Glasgow) G W Ireland (Pathhead) K A Mackay (Laggan) T S McDonald (Glasgow), J G Munro (Beauly) David Myles (Forfar) R A. B Rorie (Dundee) C S Sandeman (Durness), J A Shearer (Bucksburn) J M Stalker (Dundee) and George Swapp (Aberdeen)

The Scottish office of the College is at Livingstone House, 39, Cowgate, Edinburgh, 1

### Course on Child and Family Psychiatry

The department of child psychiatry of Ipsw group is holding a refresher course on this March 28 to April 1 Further particulars may b the Child Psychiatry Clinic, 11, Fore Street, Ipsw

### International Symposium on Cardi

A symposium on Cardiovascular Surgery in Physiology, Diagnosis, and Techniques is to b Detroit on March 17–19 Inquiries should be the secretary of the symposium, Henry Ford Hosp 2, Michigan, U S A

### Royal Institute of Public Administration

This institute is to hold a conference, under the ship of Dr May Baird, at Peebles from March 31 on the National Health Service The theme of ference is to be Working Together—Progress and The opening speaker will be Sir Humphrey chairman of the South Eastern Regional H other speakers will include Dr J O McDonagh, the Scottish Association of Executive Councils, Jardine, chairman of the General Board of Dr M M Whittet, physician superintendent of Hospital, Inverness Further particulars may b the hon secretary of the Edinburgh and East of regional group of the institute, 245, High Street,

### Lady Tata Trust

The trustees of this fund invite applications scholarships, or fellowships for research on blood, with special reference to leukæmia In affinity between leukæmia and other forms of disease, candidates who wish to undertake aspect of malignant disease which may throw light on problems of leukæmia will be eligible

Grants are made for research expenses or to provi or technical assistants for senior workers Scholarships of £600 per annum) are awarded for the personal of workers carrying out approved research under su In addition the trustees may award one or more fellow p a ) to workers with considerable research experien particulars may be had from the secretary of the sci committee c/o Medical Research Council, 38 Old Q London, S W 1 Applications must be submitted before

### Dinner to Dr W E Lloyd

On Jan 15 Dr Lloyd's former house physic Westminster Hospital and the Brompton Hospital Chief a dinner Despite bad weather 45 gathered from all over the country The occasion was by any special anniversary, but by the hosts wish their "affectionate regard for the most wise and physicians" Dr Lloyd included in his list of ideal a houseman—loyalty, enthusiasm, and a calm understanding of human nature (including the All these found expression in speeches extolling the figure known throughout his hospitals as 'Erne

ommon knowledge that tuberculosis in children ventable disease yet by the time children in reach their fourteenth year some 45% of them n infected with tuberculosis (Medical Research 1952) The mortality from tuberculosis in child fallen rapidly in the last few years largely as of improved methods of treatment, but the *fall* culosis morbidity has not kept pace with the ortality (Lorber 1953) For this reason we have detailed investigation of the source of infection e group of tuberculous children This was on lues to a smaller investigation of 150 children erculous meningitis or miliary tuberculosis which ented by one of us to the British Pædiatric on (Lorber 1950)

the present investigation we were repeatedly d by the frequent occurrence of certain prevent les of infection in children and it is these which put together for the purpose of this paper

### Material and Method of Study

otal of 564 children with active intrathoracic or ed tuberculosis there were 367 (65 2%) in e source of infection was determined A really search for the source of infection was made in ese 564 children—the search including the whole d together with persons who on the basis of ry appeared to be likely sources of infection n source of infection was finally discovered in these 401 children (81 5%) (see table) The were either inpatients in the Children's Hospital eld between Jan 1 1947 and Dec 31 1952, or nts attending the tuberculosis contact clinic in dren's Hospital between 1940 and 1952 inclusive e 401 patients were admitted because of miliary geal tuberculosis. 73 of the 401 children (18 2%) der one year of age and 101 (25 1%) were one and two years of age Information regarding ce of infection was collected up to and including 1954 For the purpose of this study entire histories were sometimes re-assessed and the re-examined with the help of chest physicians

evidence that a child has been infected by a uberculous person can never be absolute When d however that an infected child had been in ed contact with a person suffering from active ary tuberculosis or with a person with an potentially discharging tuberculous lesion we that person as the source of infection. Some ore than one such person was in contact with In other cases the chest physician reported that in contact with a child had recently had an ous which was now quiescent If no other definite was discovered then such persons were accepted as probable sources of infection Hearsay evidence of contact with tuberculosis or of contact with a person with a chronic chest infection of doubtful ætiology was not accepted as evidence of contact with tuberculosis, nor were other children suffering from uncomplicated primary tuberculosis accepted as sources of infection

### Summary of Results

The source of infection was determined in 327 of the 401 children (81 5%) who were adequately investigated. It is known that in some of the children in whom no contact was found the infection was of bovine origin

As one would expect the younger the child the easier it was to trace the source of infection In the adequately investigated families the source of infection was found in 70 (95 9%) of 73 children under one year of age in 86 1% of the 101 children aged one year in 84 6% of 117 children aged two to four : and in 64 5% of 110 children aged five to fourteen In some cases there were multiple contacts The father had tuberculosis in 119 instances the mother in 108 other relations in 143 and other persons in 46 It is apparent that most of the sources of infection were within the household for over three quarters of the contacts were parents or other persons living in the house

### Observations on the Results

From our knowledge of the source of infection in the above children we have brought together some of the more important means at our disposal for preventing tuberculous infection in children We have arranged these under headings illustrating most of the headings by one or two stories to show the consequences of lack of attention to detail in the measures indicated All these stories could be repeated many times We do wish to emphasise that these stories are not given in any spirit of criticism their sole purpose is to emphasise the importance of the measures described in the prevention of tuberculosis They represent failures, and in giving them we are not at all unmindful of the tremendously valuable work of the tuberculosis services in the prevention of infection The following are the measures which we wish to emphasise

THE SOURCE OF INFECTION OF 564 CHILDREN WITH INTRATHORACIC OR GENERALISED TUBERCULOSIS
(Adequately and inadequately investigated families)

| — | Contact found | | | No contact found |
|---|---|---|---|---|
| | Known beforehand | Discovered afterwards | Total | |

(1) *The avoidance of delay in radiological examination in the presence of symptoms suggestive of tuberculosis*

Though active tuberculosis in an adult can be asymptomatic, in our experience symptoms were usually present but their significance was not realised and there was serious delay in arranging radiological examination For example a man was treated at home for pneumonia for six months, and apparently no doubt was felt about the diagnosis It was only when his two year old boy was admitted to hospital with tuberculous meningitis that he was X rayed and found to have tuberculosis. A mother of two young children had had a cough for five years and had been treated for chronic

---

nt of a grant from the Tuberculosis Research Fund of the rsity of Sheffield bronchitis She was unduly tired during pregnancy, and it was some months after delivery before she was X-rayed on her own initiative by a mass-radiography unit, and found to have tuberculosis By that time both her children had been infected

(2) *Determined and persistent efforts to persuade a suspected contact to have a radiological examination*

One by one all 14 children of a family contracted tuberculosis and 2 of them died The father had a chronic cough, but he refused an X ray examination on the grounds that he was "too nervous" to have that done No-one other than a health visitor had attempted to persuade him

(3) *Notification*

Many tuberculous persons—children and adults—are not notified Cases of tuberculous cervical adenitis, or of tuberculosis of the kidney, bones, or joints are particularly liable to be left unnotified Quite often a case is not notified because of the erroneous belief that someone else has done it Sometimes notification is avoided because it is felt that such a step might expose the patient to a social stigma or handicap him in other ways, such as obtaining jobs, or in obtaining life-assurance policies after recovery In other cases evidence of activity of the tuberculous process is in doubt A positive tuberculin reaction as the sole evidence of tuberculous disease is not acceptable to the authorities as a reason for notification, although it is obvious that the notification of young children with a positive tuberculin reaction may well lead to the discovery of an open case of tuberculosis Sometimes notification is missed simply by default There would seem to be good grounds for establishing a modified form of notification, which would not expose the patient to any possible disadvantages, and yet would allow the chest physician to examine for the source of infection and protect other contacts

(4) *Continued supervision of adults who are thought to have inactive tuberculosis*

A diabetic was examined at a chest clinic when his five year old, daughter was notified as a case of primary tuberculosis He was found to have an "inactive apical nodular fibrosis" and was discharged from the clinic Subsequently he developed backache and had hæmoptyses, but he was not re examined until another child, who had not been born when the man was first seen, developed tuberculous meningitis Another four month-old baby in this family also became infected and developed meningitis The father was now found to have advanced tuberculosis, and he died in spite of treatment

There is often delay in the diagnosis of tuberculosis in diabetic patients The special liability of diabetic subjects to develop tuberculosis is not always remembered, so that routine X-ray examination is not done

(5) *The treatment of "sputum negative" adult sufferers as potentially infectious if they are in contact with children*

We frequently found that children had become infected with tuberculosis because it was assumed that the adults with whom they were in contact were non-infective because the sputum was "negative" In some cases only a single specimen had been examined As a result of reliance on this laboratory finding, the children were not given protection by B C G Many of the patients, furthermore, were under the impression that they had not got tuberculosis at all

A non tuberculous child had a chronic medical ailment necessitating visits to hospital twice weekly for several months His mother complained that she and her child had every week to share an ambulance with adult patients who were being taken to a sanatorium for refills for their artificial pneumothorax This statement was confirmed by the local authority, who assured us the patients were "sputum negative"

(6) *Determined efforts to avoid the tuberculosis by children from neighbouring the homes of infected adults to watch television with their children, or for other purposes*

We know of several instances of families of ill patients acquiring a television set for th ment Unfortunately the children in the learn about it and gather round the set As a of this, we quote a letter from a chest physi to our inquiry about the contacts of a boy culous meningitis

> " the mother and father in this case have and are normal There seems little doubt that probably became infected at a neighbour's ho frequently went in to see the television and m we have a positive case of tuberculosis As a matte we have another boy of thirteen with a pleural also went and enjoyed this television "

(7) *The prevention of tuberculin negative ch acquiring tuberculosis while attending chest cli clinics, or hospital outpatient departments*

Children may contract tuberculosis while chest clinics and hospitals for contact other reasons In many such clinics there are for keeping uninfected children away from attending such clinics Furthermore, adults tuberculosis often have to take their children tion, because there is no one else to take them we know of several examples of infection by t but it is impossible to prove such infections

An example of this was brought to light wh was referred to one of us from an infant we because of a behaviour disorder It transpir mother had chronic pulmonary tuberculosis a in sanatoria on more than ten occasions. He was taken away from her for three months a nursery until B C G vaccination had been After that she regularly attended an ordina clinic with her baby and freely mixed with oth and babies who had not had the benefit of B C tion and who were unaware of the danger to were exposed The attention of the medica health was drawn to this case He matter further and found that 34 mothers attended with their infants the ordin clinics in his area and freely mixed with oth This practice has now been discontinued

We are fully aware of the difficulty of uninfected children from coming into co infected adults in chest clinics, but it can nea be done with proper arrangements and fores

(8) *Full and adequate instructions of infect elementary hygiene*

When tuberculous adults had to wait for to a sanatorium, or were discharged from a after treatment, we often found that they had no instructions in elementary hygiene as re sputum and did not realise that they wer from an infectious disease A young woman monary tuberculosis and tuberculous laryn offered to look after a young baby while t went out to work, not knowing that she was harm The child contracted miliary tubercul

The responsibility for health education is of the chest physician, partly that of the fa and partly that of the health visitor It is a opinion whether there should be special t health visitors or not, but it would seem that place for more intensive training of health vi important aspect of tuberculosis prevention

(9) *Instruction of parents in the importance of their children from coming into contact with kno from the disease*

adfather was admitted to a sanatorium with sis While an inpatient there he repeatedly is daughter's home (which was not his own nd as a result he infected his seven year old ld who developed miliary tuberculosis

*he avoidance of unnecessary contact of an infected h children*

ten found that tuberculin negative infants and were allowed to visit relations in tuberculous hospitals and sanatoria This could certainly be Patients under treatment were allowed to go weekends and holidays using public transport ct their children or the children of friends or who had not been protected by B C G

*rotection of tuberculin negative children by B C G are known to be about to be exposed to tuberculosis further contact cannot be prevented*

were discharged from sanatorium after treat thout steps being taken to prevent contact with or without protecting the children by B C G only when an adult was found to have tuber no *immediate* effort was made to determine children in the family were still tuberculin in order that they could be immediately from further contact and given B C G Instead continued contact was allowed even nursing being allowed to continue to breast-feed their

*dequate segregation of children from contact ng given B C G*

und that some children were undergoing B C G ion without segregation from an infectious adult *tion is irksome and occasionally difficult to* but it is almost always possible Failure to e a child from contact for six weeks before sion and until tuberculin conversion after vaccina oses the child to infection and gives the parents a se of security It is a practice which brings accination into disrepute

## Discussion

ave made no attempt to give a comprehensive of all the various measures which are important revention of tuberculosis in children We have not d for instance the provision of safe milk We owever picked out from our experience certain s which we think need re-emphasising in that ften see tragedies because these measures have n applied, or because there was *delay in their* ion We are convinced that a greater sense of is needed When a child is notified as having l tuberculosis *every possible effort should be made tely to determine the source of infection, however* That this is very well worth while is convin emonstrated by our figures The source of infection monstrated in 81% of 401 children who were ately' investigated—*thus making it possible* the infected adult to prevent further dissemina infection among children and others and to immediate contacts by B C G if they had not been infected

act that the source of infection could be found in f the children under one year of age is of particular nce. It is of equal importance that in the older p—namely in children five to fourteen years old rce could be found in 64 5% of the cases The nce of this latter fact lies in the attitude so often that in the case of the older child the possible of infection are so numerous that it is hardly while making the effort to look for them Our belie that idea We think it extremely likely, nore that with still more vigorous efforts our for the frequency with which the source of infection was found could be quite considerably improved We think that the figures would be improved by examining other contacts, when examination of the immediate family has proved negative

Just as it is essential when an infection in a child is notified, to look immediately for adult contacts so it is essential, when an adult is found to be infected with tuberculosis to conduct an *immediate* examination of all child contacts, so that further contact can be prevented if the child is still tuberculin negative and he can be protected by B C G if subsequent contact is unavoidable A real sense of urgency is vitally necessary if further tuberculosis is to be prevented

We have re-emphasised the importance of instructing infected patients in the elements of hygiene with regard to their sputum and in particular with regard to their infectivity All too often one sees tragedies in the way of serious infections in childhood which have arisen simply because an adult with tuberculosis was unaware that he was infective particularly to children

The value of the work of the tuberculosis services is reflected by the remarkable fall of childhood tuberculosis mortality in Sheffield (Lorber 1953) It was shown that the mortality in childhood from tuberculosis was lower in Sheffield in 1951 and 1952 than in any other city (The mortality in 1953 remained the same as in 1952 —namely 1 8 per 100,000) We draw cases however from a very wide area, and there is still a great deal of morbidity due to tuberculosis in Sheffield and in the surrounding region Much of it can be prevented by further vigorous and determined efforts.

## Summary

A search was made to determine the source of infection in 564 tuberculous children suffering from intrathoracic, miliary or meningeal tuberculosis The source of infection was determined in 307 children (65 2%) but what was considered to be an adequate search for a contact was made in only 401 cases

In the 401 adequately investigated cases the source of infection was found in 327 children (81 5%) It was found in 95 9% of 73 children under one year of age, in 86 1% of 101 children aged one in 84 0% of 117 children aged two to four and in 64 5% of the 110 children aged five to fourteen

It is very important to notify all cases of childhood tuberculosis so that an intensive search for the source of infection can be made This enables the infected adult to be treated and other child contacts to be protected from infection by B C G or other means It is also important to examine all child contacts immediately when an adult is found to have tuberculosis so that tuberculin negative children can be segregated until they have been protected by B C G We feel strongly that a greater sense of urgency is required in these preventive measures

Other anti tuberculosis measures which require far more attention are

(1) Chest X ray examination of all adults with symptoms that might be due to tuberculosis.

(2) Chest X ray examination of all adults who may be a source of infection

(3) Continued supervision of adults whose tuberculosis is supposed to be inactive Former patients who are "sputum negative' should be regarded as potentially infectious if they are in contact with children.

(4) Prevention of contact between unprotected children [illegible] adults with tuberculosis. Tuberculin negative children [illegible] be *excluded from tuberculous wards of hospitals an* [illegible] at visiting time

(5) Instruction of adult patients in the infective [illegible] condition and in elementary hygiene

We have also mentioned the value of [illegible] who cannot permanently be prevented [illegible] contact with infected adults

We wish to thank all the numerous chest physicians from a wide area who have taken part in the search for contacts of affected children We are particularly indebted to Dr H Midgley Turner, chest physician at Sheffield, for his great help and for reading and criticising this paper without his aid the investigation would have been impossible To Dr Llewellyn Roberts, medical officer of health for Sheffield, we are grateful for reading this paper, and for his coöperation Prof Alan Moncrieff kindly read and criticised the paper We also thank all the health visitors who have done so much essential work in the search for contacts

## THE SPECIAL SIGNIFICANCE OF CONCOMITANT GASTRIC AND DUODENAL ULCERS *

H Daintree Johnson
M B Camb , F R C S

SURGEON, ROYAL FREE HOSPITAL , LECTURER IN SURGERY, POSTGRADUATE MEDICAL SCHOOL OF LONDON

THOUGH duodenal and gastric ulcers have much in common, causing similar symptoms and having similar histological appearances, there are quite striking differences between the sorts of people who are attacked by the two lesions Not only are there well known variations in age, sex, and racial distribution, but also the patterns of gastric secretion and muscle tone exhibited by duodenal and gastric ulcer patients lie at opposite ends of the scale , for, whereas duodenal ulcer develops on a basis of hypersecretion of acid, hypertonicity, and rapidity of gastric evacuation, gastric ulcer is associated with a rate of acid secretion below (on the average) that of normal subjects, and with stomachs which are sagging, sluggish, and slow in emptying

That duodenal and gastric ulcers may nevertheless be sometimes found together has been held by some to be evidence of common ætiological factors, for concomitance is twice as frequent as it should be on chance alone Indeed, if they have similar origins, gastric and duodenal ulcers might be expected to occur together not infrequently in persons whose anatomical and functional characteristics lay midway between those associated with each ulcer alone But these are not the sort of people who get such dual lesions

My own opinion, however, is that, whereas the main cause of duodenal ulcer is disproportion between the amounts of acid and alkali reaching the duodenal bulb, the main cause of gastric ulcer is gastric hyposecretion, with its attendant hypomotility On this basis one would expect ulcers of the two organs to be mutually exclusive, and in cases of concomitance some special factor would have to be at work The present investigation was undertaken to discover what this factor might be

### Incidence of Concomitant Ulcers

Though single instances had been recorded previously (Mix 1913, Bonchut and Durand 1913), Sir David Wilkie (1926) seems to have been the first to draw attention to the comparatively frequent coexistence of ulcers in stomach and duodenum He reported that in a series of 300 of his own patients he had found combined ulcers in 42, 16% of those with duodenal ulcers also having gastric ulcers and no less than 53% of the 79 gastric ulcers being associated with duodenal ones The burden of Wilkie's paper was his suggestion that undiagnosed concomitant gastric ulcer might be a reason why gastro enterostomy did not always relieve symptoms attributed ulcer

Little attention was paid to Wilkie's figu though they were , indeed even to the pre coexistence of gastric and duodenal ulcers se struck no-one as remarkable, and scant refer to be found in the most recent and comprehe on peptic ulcer

Hurst and Stewart (1929) described chronic ulcers or scars in both organs as infrequent " and referred to 4000 post morte tions at which 173 chronic gastric and duodenal ulcers were found, but of wh revealed associated ulcers (5 5%) They these figures were difficult to reconcile wi Wilkie

There is no doubt, however, that Wilkie l alone and that the experience of many other continued to be different from that of ph radiologists as well as that of pathologists because concomitant ulçers are more nume patients whose symptoms are severe and and who are therefore referred for operatio

Some 10–15% of peptic ulcers, it is said, ar able radiologically, and I have myself opera patients with peptic ulcers which had not on repeated X-ray examination—including a gastric and a duodenal ulcer The effect proportion of ulcers at radiography is to apparent frequency of concomitant ulcers. if 15 ulcers were missed among 100 patients, had both kinds of ulcer, the apparent rate of would be reduced from 10 to 8%

Though physicians tend to see the earlier surgeons the late ones, the greater frequency tant ulcers in surgical practice cannot at f explained by the longer duration of the illn proportion of ulcer cases with a double le at necropsy Nowadays perhaps most pati condition lose their stomachs before they re mortem room, but this was certainly not so Hurst and Stewart reported The discrepan arises through the discovery, after death, of (as well as some larger) solitary ulcers who was not suspected during life , and the ulcers (most of which will already have clinically) form a smaller proportion of the bigger total The figure for concomitance pathologists before the period of widespread is likely to be the truest one for the living a the dead

TABLE I—AGE AND SEX DISTRIBUTIO

| Age groups | Numbers |
|---|---|
| Under 30 | 2 |
| 30–39 | 13 |
| 40–49 | 34 |

## The Present Series

ng my own 311 patients operated upon for peptic 9 (9%) have had lesions of both stomach and um 1 in 7 duodenal ulcer patients has also had r ulcer and 1 in 4 gastric ulcers has been associated duodenal one

lin (1954), in a longer series has observed similar ions though in other published series of operation here figures for concomitant ulcers have been ey have varied widely and have commonly been 1 in 20, corresponding with what may be the true nce as shown by the earlier post-mortem data , indeed in a large series of gastrectomies the ion of double lesions may be regarded as an index verage severity of the cases referred to the surgeon ed

he purpose of this investigation my own group ases has been supplemented by a further 90 vailable to me by my colleagues Sex and age tion were as shown in table I

*f Appearance of the Lesions* (table II)

cases both the duodenal and gastric lesions were when the patient was first investigated (or if radiographs had been taken these could not ed) In 6 cases radiography never showed either nd there was no dependable evidence as to which veloped first

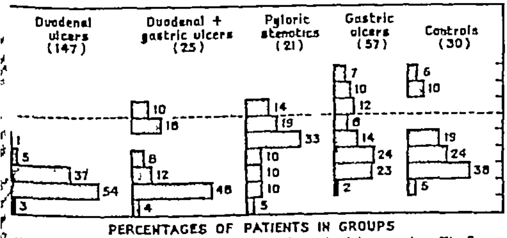
of the remaining 85 cases the duodenal ulcer was red first, either by X ray examination or because rated Review of early X ray pictures on which e ulcer was reported has not been possible in all ut 43 have been reconsidered in the light of later ments and no hint of a gastric ulcer has been n any of them

nly 6 patients was the gastric ulcer detected by aphy before any suggestion of duodenal ulcer served Reappraisal of the pictures in these cases d the appearances of absolute normality of the al cap in none though the irregularities were small ght well have been thought unconvincing In 5 e cases an old healed duodenal scar was found at on

tients (18%) had had perforations in the past and e had been duodenal

*n Pattern*

it is patients of the duodenal ulcer type and not of the gastric ulcer type who develop combined ulcers would be expected from the fact that it is usually if not always the duodenal ulcer which appears first This is further confirmed, however by secretion investigations The majority of those with two ulcers who were suitably investigated showed evidence of acid hypersecretion and in some cases this was gross (table III and fig 1) In a number of cases it was noticed that though the volume and total acidity of the juice was high, free acid was low or absent, signifying a large degree of intragastric buffering This is characteristic of gastric retention and conformed with my observation that pyloric stenosis had been a feature of many of my own cases of concomitant ulcers



icrogrammes of ionised hydrogen in whole of gastric night secretion. The figures e concomitant-ulcer group are seen to lie between those for duodenal ulcer and loric stenosis

### *Gastric Emptying*

At fluoroscopic observation of gastric emptying it is seen that barium passes through the pylorus ahead of each wave of peristalsis, and that this happens whether or not these waves meet across the lumen of the antrum But when they do not do so it is evidently impossible for them to exert much pressure and the pressure gradient required to cause the barium to pass through the pylorus must be produced mainly by a difference in tone between stomach and duodenal cap As the wave of peristalsis reaches the duodenal cap and begins to affect it the pylorus closes and the cap contents are therefore forced on into the rest of the small bowel The mechanism is not unlike that of the heart—the stomach resembling a giant auricle the duodenal cap behaving like a little ventricle going into systole and diastole and the pylorus taking the place of the mitral valve

TABLE III—ACID SECRETED AT NIGHT

| Milli-equivalents free HCl in bulked all night juice | Percentages in groups | | | | |

| 100–109 | 1 | | | | |
| 110– | 1 | | | | |

D U = duodenal ulcer G U = gastric ulcer
D G U = duodenal and gastric ulcer Pyl st. = pyloric stenosis

Patients with concomitant gastric and duodenal ulcer are seen to have secretion patterns between those of patients with duodenal ulcers and those of patients with well-established pyloric stenosis and less like that of patients with gastric ulcers

From these observations it is not unreasonable to argue that an ulcer or scar involving the pylorus or any part of the duodenal cap is bound to reduce the efficiency of gastric emptying to a greater or lesser degree It is well known that duodenal ulcers occur in persons whose stomachs show excessive vigour and activity of all kinds muscular as well as secretory and that before an ulcer becomes established they display rapid gastric emptying Initially the exaggerated gastric tone may compensate for incomplete cap diastole due to scar but later the gastric emptying becomes slowed entering first the range regarded as normal and then that classed as gastric retention

### *Gastric Retention*

Pyloric stenosis and chronic gastric dilatation having been noted in a number of cases of concomitant ulcers retro spective analysis of all the others from this point of view was next undertaken

In 36 cases this was unrewarding Though even a small duodenal lesion may slow down gastric evacuation markedly, quite a large and callous one may give no certain evidence of having done so Many of these 36 patients had complained of vomiting and fullness during attacks, but none had reported regular and copious vomiting, none had been noted to have evidence of a dilated stomach or a succussion splash, and of none did the radiologist happen to have estimated the emptying-time For what it is worth, 29 of the 36 had had gruel or histamine test-meals, and these showed to a greater or lesser extent the "climbing" type of curve said to indicate gastric retention

In the remaining 76 patients (64%) there was incontrovertible clinical and radiological evidence of gastric retention, and in 39 (33%) well-marked pyloric stenosis was found and remarked upon at operation

Thus 64% of the patients with concomitant ulcers unquestionably had gastric retention, and most of the rest may have had it

The notes of all adult patients who had been in the Royal Free or Hammersmith Hospitals with pyloric stenosis during the past ten and past sixteen years respectively were now reviewed This diagnosis had been recorded for 331 patients and of these 52 (16%) had also had gastric ulcers, either found at radiography or discovered at operation or necropsy Some (1 in 5) of the latter had not been revealed by X-ray examination, and it is notorious that gastric ulcers are more difficult to demonstrate radiologically when there is pyloric stenosis and gastric retention When only patients who underwent surgery or who came to necropsy are considered the proportion of those with gastric ulcers rises to 19%

The evidence suggests that in at least 2 out of 3 cases of concomitant ulcer gastric retention is a main cause of the ulcer, and that of every 6 patients admitted to hospital with pyloric stenosis a gastric ulcer has already developed in 1 One is naturally led to question whether the slow rate of gastric emptying associated with this disease may not be a factor in the ætiology of all gastric ulcers

*Operative Findings* (table IV)

91% of the gastric ulcers were active, many were huge, 10 were bleeding, and 1 was perforated as well as bleeding

TABLE IV—FINDINGS AT OPERATION (110 CASES)

| Duodenal ulcer | Gastric ulcer | Numbers | % |
|---|---|---|---|
| Healed | Healed | 3 | 3 |
| Active | Healed | 6 | 5 |
| Active | Active | 26 | 24 |
| Healed | Active | 75 | 67 |
| Stenosis | Active | 32 | 29 |
| Stenosis | Healed | 1 | 1 |

The most frequent combination found (67%) was that of an active gastric ulcer and a healed, scarred, often stenosed duodenal lesion Both ulcers were active in 22%, both were healed in 5%, and in the remaining 6% an active duodenal ulcer was associated with one or more scars on the stomach The great frequency of healed, scarred duodenal lesions conforms with the other evidence that this is the older lesion Just as clinical pyloric stenosis is more often seen in patients with old healed ulcers than with open ones, so gastric ulcers are seen more frequently in association with healed than with active duodenal lesions

*Further Evidence from Additional Special Cases*

In 2 cases of gastric ulcer no sign of old duodenal ulcer was seen but the pyloric ring was observed to be ly thick and tight The specimens were

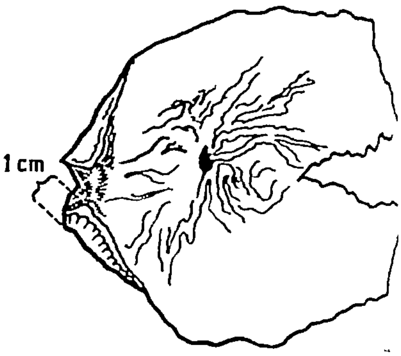

Fig 2—Three-quarters of a stomach resected for chron
The specimen shows the ulcer and massive ,
of the pylorus which had the feel of cartilage. (In a
specimen this degree of thickening would not, of
remarkable.) (Tracing of a photograph)

considered to be instances of adult hypertroph
stenosis (fig 2)

6 cases have been collected in which gastr
tomy had been performed some years ago for d
ulcers and in which recurrent ulcers had occ
ther surgery All patients were found to hav
ulcers, all had old scarred duodenums, 3 had
jejunal ulcers and 3 were observed to have
narrowed stomas and dilated stomachs.

Another patient had been submitted to gastr
tomy for duodenal ulcer in 1947 In 1949 this
undone Four months later I performed an
gastrectomy for a bleeding gastric ulcer and a
duodenum was observed The stomach disten
blood was unusually large This patient had ble
times

Having begun to suspect that pyloric
cause a gastric ulcer and having observed the
with which prolonged gastric retention follows
tomy, I wrote in 1947 "the author believes hyp
to be a main ætiological factor in a proportion
to the left of the angulus It may well be th
ulcer will prove to be one of the late compli
vagotomy in man" (Johnson 1948) Since the
choly prediction, a number of such ulcers
vagotomy have been reported and 4 have com
my own experience All 4 patients had healed
ulcers with much scarring, and all 4 had gross
gastric emptying and greatly dilated stomachs.

It might be thought that the acid h
characteristic (as is seen) both of patients with
ulcers and those with concomitant ulcers was
in the ætiology of the gastric ulcer, and indeed
be so However one final case may show that
an essential one, for this patient had a carcino
antrum obstructing the pylorus, a benign gast
proximal to it, and achlorhydria

## Peptic Ulcer and Hiatus Hernia

The association of peptic ulcer with hiatal h
now well recognised (Belsey 1952) Harrington
coincident gastric ulcer to friction on the lesser
of the stomach as it passes back and forth
margin of the œsophageal hiatus of the d
The coexistence of duodenal ulcer has
explained.

In a series of 30 patients with hiatal herni
met 4 with gastric ulcers, 4 with duodenal ulcers
with both a gastric ulcer and a healed, scarred d
ulcer, and this association can be linked w
has emerged concerning concomitant ulcers.

Hiatal hernias are of two main kinds—rolli
œsophageal and sliding or "short œsophagus ty
latter is associated with reflux œsophagitis, di

y and by œsophagoscopy, the former is usually

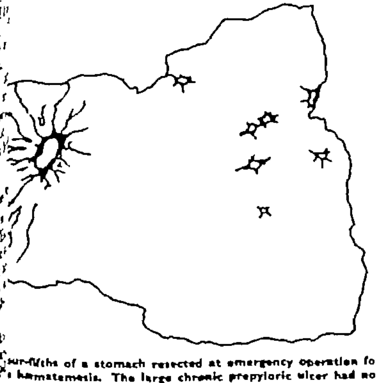
hiatus hernia is supposed to undermine the nce of the œsophago-gastric valve or sphincter nerally thought to be the cause of the reflux gitis. For a number of years the shortness of the gus and the accompanying thoracic stomach were d as congenital anomalies. But a congenitally d organ ordinarily draws its blood-supply from y source; indeed the short, tight vessels often surgical alteration of its position Such a state is not seen in hiatus hernia and on one occasion ble to reduce with ease at operation a hernia in he whole stomach and most of the transverse ccupied the right side of the chest It is now y accepted that most if not all short œsophaguses uired

ctically three groups of factors could contribute ation of a hiatus hernia; those which relax the of the hiatus in the right crus, those which affect sure gradient between abdomen and thorax, and hich control tone in the longitudinal muscle of phagus In the rolling type of hiatus hernia in he cardia remains below the diaphragm evidently e first two factors can have operated. In the type I believe œsophageal spasm to be paramount observed for 4½ and 5½ years, two patients ll marked reflux œsophagitis in whom hernias ly absent, have recently appeared and enlarged erefore hold that, in at least a proportion of cases g hiatus hernia incompetence of the œsophago valve or sphincter is the first cause, and reflux gitis with œsophageal spasm the second cause of iation

athognomonic symptom of reflux œsophagitis is rn This symptom is common in duodenal ulcer n indicates that there is reflux into the gullet of e often the excessively acid gastric contents The retention which characterises active duodenal the probable cause of this tendency to œsophageal But if reflux œsophagitis can cause hiatus hernia ested, the likely reason for the occasional dis of duodenal ulcer and hiatus hernia together is t.

ic retention has been shown sometimes to result stric ulcer and I suggest that in some cases of nt gastric ulcer and hiatus hernia gastric retention h the predisposing cause of both

y own series of hiatus hernias of the short gus" type evidence of delay in gastric emptying n found in 47% including all 9 cases in which ere coincident peptic ulcers



ur-fifths of a stomach resected at emergency operation for hæmatemesis. The large chronic prepyloric ulcer had not it had caused pyloric obstruction by scar *The hæmorrhage* om acute gastric ulcers several of which contained blood-clot, were impalpable from outside the stomach. (Tracing of a aph.)

## The Prognosis in Combined Ulcers

With coexisting gastric and duodenal ulcers, the risk to the patient is greater than the sum of the risks from either ulcer alone Hæmorrhage specially from the gastric ulcer is common in all 10 patients in my series who were admitted to hospital actively bleeding, the blood came from the gastric ulcer Of the patients with gastric ulcer alone admitted during the same period to the hospitals from which the series of concomitant ulcer is drawn 8% had bled at some time in the past but among those with concomitant ulcers no less than 47% had at some time had major hæmorrhages and 20% had had several.

In an analysis of 3000 post-war elective gastrectomies which forms part of a separate study the over all mortality was found to be 4% The death rate among those with combined ulcers was 10% and this was not attributable to a difference in age distribution In the present series of 119 cases there were 12 deaths in hospital

## Treatment

In the treatment of patients with combined gastric and duodenal ulcers it is important to bear in mind two facts

(1) An element of gastric retention is almost certainly present and this indicates special preoperative measures, such as gastric decompression and lavage and particular attention to likely depletion of water electrolyte, and protein reserves

(2) The patient is of the duodenal ulcer type and likely to be capable of acid hypersecretion, even though this is not always evident in the presence of pyloric obstruction I have often advocated moderate resection for gastric ulcers in the belief that, since hypersecretion is not a feature of these patients, radical resection is unnecessary provided that all diseased tissue is removed (Johnson 1950, Johnson and Orr 1954) For combined ulcers, however as for duodenal ulcer, *an operation adequate to control hypersecretion must be performed*

When a patient is operated upon for urgent hæmorrhage and evidence of a duodenal ulcer is seen it should not be assumed that this is the source of the hæmorrhage particularly if the duodenum is much scarred for in such a case there is a substantial chance that the bleeding is coming from a concomitant gastric ulcer sometimes as in 3 of my cases an impalpable one (fig 3)

Patients with gastric ulcers who have symptoms such as heartburn or vomiting should be suspected of gastric retention and should be especially investigated from this point of view

The reason why sleeve resections for gastric ulcer were followed by recurrences is I suggest that gastric retention followed the denervation of the distal part of the stomach and the pylorus

It is now often stated that though gastrectomies for duodenal ulcers may occasionally be followed by stomal ulcers, recurrences after resection for gastric ulcers are almost unknown However though I favour and have had good results with Billroth I gastrectomy for gastric lesions I predict that its present widespread revival and popularity will lead to recurrent gastric ulcers due to its use in some unsuitable cases where the creation of only small and inadequate stomas has been possible

Finally I would urge that concomitant gastric and duodenal ulcers are too dangerous to warrant non operative management and that surgery should be resorted to early before the risks become excessive

## Summary

Gastric and duodenal ulcers occur in quite different sorts of people The question therefore arises why ulcers should sometimes be found in the stomach and the duodenum of the same patient

The incidence of concomitance of duodenal and gastric ulcers is probably about 5% if symptomless ulcers are included Of ulcer patients who come to hospital for

investigation about 7% have both duodenal and gastric lesions Surgeons, however, commonly see a greater proportion of such patients, and there were 9% in a surgical series of 311 cases

Analysis of a series of 119 cases of concomitant ulcers yielded the following facts

1 The duodenal ulcer is the first to appear

2 The patients have a secretion pattern which lies between that of patients with duodenal ulcer and that of patients with established pyloric stenosis It is much less like the secretion pattern of gastric ulcer patients

3 A substantial majority of patients with concomitant ulcers have gastric retention and many have gross pyloric stenosis Some 16% of patients admitted to hospital with pyloric stenosis have gastric ulcers as well.

4 At operation the commonest finding is an active gastric ulcer and a healed, scarred duodenal one

12 additional cases are described which illustrate how gastric retention from causes other than duodenal ulcer may also be complicated by the development of gastric ulcers

9 cases are reported of peptic ulcers associated with hiatus hernia It is suggested that reflux œsophagitis may sometimes cause hiatus hernia (instead of vice versa) and reflux may in turn be caused by duodenal ulcer and gastric retention Gastric retention may also apparently cause gastric ulcer, and the association of these lesions may be thus explained

Patients with concomitant ulcer are particularly prone to have hæmorrhages, and when they do it is usually the gastric ulcer which bleeds

Once concomitant ulcers have become established, elective surgery is four times more dangerous than in cases of solitary ulcers

The bearing of these observations upon the treatment of patients with concomitant gastric and duodenal ulcers is discussed

# RADIOTHERAPY OF CUSHING'S SYNDROME

J F P SKRIMSHIRE
M D Camb , M R C P
SENIOR MEDICAL REGISTRAR, ST THOMAS'S HOSPITAL, LONDON

It is now well established that the signs and symptoms of Cushing's syndrome are caused by adrenal cortical overactivity This may be due to an adrenal cortical tumour, but bilateral cortical hyperplasia is more commonly found, and it is widely thought that this is due to increased pituitary adrenocorticotrophic activity

When no tumour can be found, treatment of the syndrome may be directed either at reducing the amount of cortical tissue by surgery or at diminishing the stimulus to cortical overactivity by irradiation of the pituitary gland

Unilateral adrenalectomy does not usually influence Cushing's syndrome significantly (Sprague 1953), but bilateral subtotal adrenalectomy and total adrenalectomy, developed at the Mayo Clinic by Priestley et al (1951) has produced excellent remission of symptoms in nearly al[illegible]ts But this operation is a considerable under-[illegible]n in skilled hands, and is often followed by chronic adrenal insufficiency, which requires treatment with cortisone

Further evidence is presented here that the p Cushing's syndrome may be arrested, and that able improvement may take place in suitable after irradiation of the pituitary gland This is simple, involves no operative risk and is not by chronic adrenal insufficiency 6 patients the last five years are reported, details of the used are described, and the assessment of is discussed

The difficulties of excluding the presence of a cortical tumour are again emphasised, but can be achieved, radiotherapy should be used initial treatment If this does not arrest or the condition, surgery may still be undertak with undiminished chances of success

## Material

The 6 patients (table I) were all females age They presented most of the features desc Cushing (1932), and additional evidence of corti function was obtained by estimation of the excretion of corticosteroids and neutral 17 ke and by measuring glucose tolerance. Cortic (formaldehydogenic) were measured by the m Corcoran and Page (1948), the normal range women in our laboratory being 0 3–0 8 mg in four hours Neutral 17-ketosteroids were mea the method recommended by the Medical Council (1951) The normal range for adult 6–18 mg in twenty-four hours Well marked and much-increased excretion of androgens an adrenal cortical tumour were not observed, there any evidence of a tumour on clinical or ra examination

TABLE I—DETAILS OF SIX CASES OF CUSHING'S S

| Case no | Age (yr ) | History | Weight (lb ) | Striæ | Hirsuties | Polycythæmia | Amenorrhœa | Blood pressure (mm Hg) | Glucos tol rance |
|---|---|---|---|---|---|---|---|---|---|
| 1 | 28 | 10 yr | +70 | + | + | + | 7 mos | 180/105 | Diabet |
| 2 | 23 | 3 yr | +20 | + | + | + | 8 mos | 160/100 | Reduce |
| 3 | 36 | 5 yr | +28 | + | + | – | 12 mos | 210/130 | Diabet |
| 4 | 33 | 1 yr | +7 | + | + | – | 11 mos | 220/150 | Reduce |
| 5 | 23 | 6 mos | + | + | + | – | 4 mos | 150/100 | Normal |
|  | 34 | 2 yr | +42 | + | + | – | 2 yr | 160/120 | Reduce |
| 6 | 19 | 3 yr | +29 | + | + | – | 2½ yr | 170/115 | Normal |

One of the patients had been previously trea radiotherapy for Cushing's syndrome and, af years' remission, a relapse following pregnancy further treatment

## Treatment

Deep X-ray therapy was given to the pituit with a high-voltage unit (250 kV peak, half va 1 75 mm of Cu) Six circular beams of X ray focal skin distance were directed at the pitui with the aid of a plaster shell through portals around the hair line A maximum dose of was given in twenty eight to thirty days, the skin dose being about 3000r Larger doses are inadvisable because of the possible developme cortical atrophy

Reducing diets were used to control obes necessary, but no other treatment was given

## Results

In assessing progress after treatment the factors were studied (table II) (1) the general ance, (2) the texture of the skin and the app

TABLE II—RESULTS OF TREATMENT

| Date | Weight (lb) | Blood pressure (mm.Hg) | Menstruation | Glucose tolerance | Cortico steroids (mg in 24 hr) | 17 Keto steroids (mg in 24 hr) | Irradiation (r) | Result |

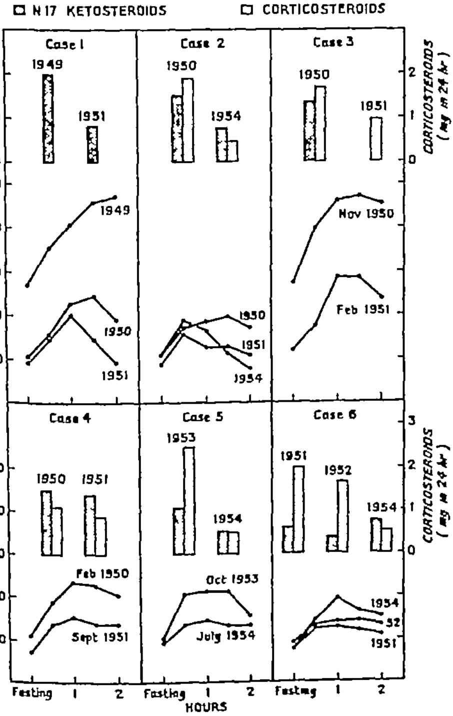
m (3) the menstrual history (4) urinary n of steroids (5) glucose tolerance and (6) ressure

f the 5 surviving patients there was considerable ment The 5th patient showed only temporary ment, but her disease has not progressed since nt three years ago



n tolerance and urinary excretion of steroids before and after treatment.

One patient died of a cerebral hæmorrhage five months after treatment was completed; she had had hypertension for many years and a vascular accident five years previously but before her death there was evidence of improvement in her Cushing's syndrome Necropsy showed mild enlargement of both adrenal cortices and hyaline changes in the pituitary basophil cells but no adenoma was discovered.

Treatment led to slow but continued improvement diminishing plethora and fading of the skin striæ usually becoming evident one to three months after the start of treatment Polycythæmia present in 2 patients disappeared during this period Hirsuties was less influenced and remains prominent in 2 patients who are otherwise normal

Menstruation became re established after a variable time in all the surviving patients but ceased again in case 6 and remains irregular in cases 2 and 5 Glucose tolerance curves showed improvement in all cases where it had been abnormal Case 1 with an originally diabetic type of curve now shows normal glucose tolerance despite failure to observe any dietary restrictions her weight remaining substantially unchanged Significant improvement was observed in the remainder (table III)

The urinary excretion of corticosteroids diminished in 4 patients but in a 5th who is clinically well the change was slight and excretion remained at the upper limit of normal The urinary excretion of 17 ketosteroids which was moderately increased in 5 patients showed significant reduction in only 2 patients

The blood pressure fell in all the patients but in only 2 did it fall to normal levels When hypertension had been present for a long time and secondary changes had taken place in the kidneys and blood vessels as in case 3 this outcome was to be expected

## Discussion

When a patient presents the appearance of Cushing's syndrome it is important to establish that this is due to adrenal cortical overactivity Obesity and hirsuties occur with hypertension and irregular menstruation in women as a constitutional abnormality The condition is not progressive and evidence of cortical overactivity is absent

No single clinical feature of Cushing's syndrome can be regarded as pathognomonic or essential to the diagnosis Although we have found the skin changes a reliable clinical indication, we have confirmed the presence of cortical overactivity by the estimation of urinary excretion of corticosteroids Absolute eosinophil-counts and the urinary uric acid creatinine ratio were not used, but additional evidence was forthcoming in some patients who showed diminished glucose tolerance and increased urinary excretion of neutral 17 ketosteroids

The presence of cortical hyperfunction having been established it is necessary to determine whether this is due to a cortical tumour A short history with rapid development of symptoms and well marked changes in the sexual sphere suggest that a tumour is present Much increased urinary excretion of androgens with an increase in the β-ketosteroid fraction may provide confirmatory evidence. In men showing well-marked feminising changes tumours are almost invariably present, and excessive excretion of œstrogen was found in 1 such case by Simpson and Joll (1938)

Clinical examination rarely reveals the presence of tumours, but they may sometimes be demonstrated by plain radiograms, pyelography, or peri renal insufflation of air Sprague (1953) points out that the tumours causing Cushing's syndrome may be very small and impossible to demonstrate radiographically In his cases tests of urinary excretion of steroids proved unreliable in distinguishing tumour from hyperplasia, and he therefore advocates exploratory operation as the only certain method of making the distinction A functional adrenal cortical tumour is associated with atrophy of the opposite adrenal gland, either of these situations being readily recognised at operation by an experienced surgeon

On the other hand, patients with long and slowly progressive histories, prominent metabolic disturbances, and little evidence of virilism are more likely to have adrenal cortical hyperplasia In these patients the excretion of corticosteroids is always considerably increased, but the excretion of 17 ketosteroids is only slightly increased and may be within normal limits Surgical exploration in these cases reveals either normal-sized or enlarged glands on both sides

The prognosis in Cushing's syndrome is poor, about half the patients dying within five years of the establishment of the diagnosis (Plotz et al 1952, Sprague 1953) Intercurrent infection, the effects of hypertension, osteoporosis, and psychological changes contribute largely to the morbidity of Cushing's syndrome In the remainder spontaneous variations in the activity of the syndrome are common, deterioration is slower and punctuated by remissions, the final prognosis depending on cardiovascular and renal changes resulting from the hypertension characteristic of the syndrome

The value of treatment is difficult to assess because of these spontaneous variations in activity and because numerous different forms of treatment have often been used in published cases It is important that progress should be adequately followed and objective evidence of improvement obtained before good results are claimed from a particular form of treatment Until recently the treatment leading to remissions in the highest proportion of cases has been irradiation of the pituitary gland Widely different techniques of treatment and dosage have been used, with variable results in different clinics, and Sosman (1949) found that only 38% of all patients treated in this way had improved Of his own 6 cases, however, 4 showed considerable improvement after radiotherapy

The serious prognosis, high morbidity, and unreliable results of previous forms of treatment in Cushing's syndrome encouraged Priestley et al (1951) to attack the condition at the adrenal level by surgical means At operation the presence or the absence of an adrenal cort[illegible] tumour can also be most satisfactorily decided When neither tumour nor atrophy (indicating of the opposite adrenal gland) is found, the recommend removal of nine-tenths of one a and complete excision of the opposite one.

This treatment is quite logical and strictly to the treatment of hyperthyroidism by subtotal ectomy Although there have been a few re of their 48 surviving patients are in rem likelihood of chronic adrenal insufficiency operation is great, and its potential dangers more serious than those of myxœdema afte ectomy Half these patients are receiving su treatment with cortisone (Sprague 1953)

Substantial improvement has resulted in 4 patients treated by the method described her considered that controlled Cushing's syn preferable existence to controlled adrenal and that radiotherapy should be used before is contemplated If this fails to arrest the p Cushing's syndrome within six to twelve months treatment can then be used with undiminished of success

## Summary

6 cases of Cushing's syndrome treated by irradiation are reported

Considerable objective improvement result of the 6 cases

Pituitary irradiation is preferable to surg initial treatment of Cushing's syndrome due to cortical hyperplasia

I wish to thank Dr H Gardiner Hill, under whose patients were admitted to hospital, and Dr W J Gr undertook the biochemical investigations, for per publish and for much helpful criticism and adv Dr I. Churchill-Davidson for details of the tech in irradiating the pituitary gland

Case 2 —A girl born on Dec 27 1951 There was no relevant family history A murmur was heard during examination because of gastro-enteritis at the age of 10 months She was not seen at Great Ormond Street till March 13 1954 when she was referred to the congenital heart clinic At this age (27 months) she could not walk and was having most of her food by bottle There was nocturnal dyspnoea; she was constipated and losing weight She was admitted in congestive failure and was given digoxin and sedatives. She responded slowly and later investigation suggested the presence of a patent ductus arteriosus and possibly aortic stenosis

*Operation.*—At thoracotomy a coarse thrill was found in both the pulmonary artery and the aorta but the ductus was sclerosed Left auricular biopsy proved the presence of endocardial fibro-elastosis and lingular biopsy showed pulmonary hypertensive vascular changes. This hypertension was also proved by the intracardiac pressures recorded at operation: right auricle 15/10 mm Hg right ventricle 74/16 mm Hg pulmonary artery 81/58 mm. Hg left ventricle 108/23 mm. Hg and aorta 109/5- mm. Hg

*Postoperatively* the patient's condition became critical Congestive failure increased despite digoxin morphine oxygen and mercurial diuretics, and she died on the eighth postoperative day

*Necropsy* revealed a large ventricular septal defect widespread endocardial fibro-elastosis involving the mitral valve dilatation and hypertrophy of all the heart chambers probe patency of the foramen ovale and postoperative fibrinous pericarditis. There was also visceral evidence of congestive cardiac failure and hydromyelia of the lumbar cord

Case 3 —A boy born on March 4 1952 There was no relevant family history Symptoms of breathlessness wheeziness and difficulty in feeding had been present from birth and he was admitted to Great Ormond Street at the age of

6 months A continuous murmur was heard by several observers and, in addition to other signs suggesting a patent ductus, his femoral pulses were absent and blood pressure was unrecordable in his legs He had severe bronchospasm, which responded well to ephedrine He was allowed home but returned a month later in extremis On his second admission there was clinical and radiological evidence of consolidation and collapse of the right upper lobe and severe bronchospasm He was given digoxin, oxygen, penicillin, and sedatives and, later because of his poor response, intravenous procainamide He still did not improve and, though intravenous aminophylline was also tried, he died about twenty four hours after admission The clinical diagnosis was coarctation of the aorta, patent ductus arteriosus, and cardiac failure precipitated by severe respiratory infection and bronchospasm

*Necropsy* confirmed the coarctation, congestive failure, and respiratory infection. There was no patency of the ductus, but endocardial fibro elastosis of the left atrium with thickening of the mitral and aortic valves was found There were also some intimal and elastic tissue changes in the coronary arteries and a very large collateral internal mammary artery

**Case 4** —A boy born on Feb 5, 1947 There was no relevant family history He was seen at Great Ormond Street about the age of 3 months because of frequent respiratory illnesses and was referred to the congenital heart clinic for cardiovascular investigation His cardiac enlargement was associated with considerable chest deformity, and he had, on most examinations, moist sounds in his chest He had no other evidence of congestive cardiac failure Cardiac catheterisation showed a higher oxygen saturation in the pulmonary artery than in the right ventricle and pulmonary hypertension (pulmonary artery 60/32 mm. Hg) These suggested a patent ductus

*Operation* —At thoracotomy right ventricular hypertrophy and a dilated pulmonary artery only were found Lingular biopsy showed hypertensive changes in the pulmonary vessels, and organising pneumonitis (probably viral in origin) was observed This latter finding adequately explained the persistent moist sounds in the chest

*Follow up* —When seen in August, 1954, the boy was fairly active, still had a trace of cyanosis, and still showed clinical and radiological evidence of collapse at his left base It was thought that the collapse might have been due in part to infection and in part to the gross cardiac enlargement He was readmitted in August, 1954, with a further respiratory infection, which responded well to antibiotics

**Case 5** —A girl born on Dec 22, 1942 There was no relevant family history Breathlessness on exertion without cyanosis had been observed since birth, and she contracted chickenpox, whooping-cough, and numerous attacks of bronchitis At the age of 2 years, during an attack of bronchitis, a cardiac murmur was heard, but she was not seen in the congenital heart clinic until the age of 8 years Although the pulmonary vasculature appeared normal on screening, there was a large pulmonary artery outline, and the other evidence suggesting a patent ductus was convincing (see table II) Finger plethysmograph and femoral artery tracings were inconclusive, but cardiac catheterisation revealed a high oxygen saturation in the pulmonary artery

*Operation* —At thoracotomy no ductus was found The left auricular appendage and pulmonary artery were seen to bulge through a defect in the pericardium (explaining the findings on radioscopy) Since discharge she has been having slight precordial pain suggesting angina but is otherwise very well The diagnosis was thus revised to a high ventricular septal defect, aortic stenosis and incompetence, and a pericardial defect

## Discussion

There are at least six well recognised causes of a continuous murmur heard over the precordium The best known is the Gibson or machinery murmur of a patent ductus arteriosus, which is loudest in the second or third intercostal space—over, or just lateral to, the pulmonary area Although the classical murmur sounds continuous on auscultation, the phonocardiographic tracing of the sound (fig 1) often begins in mid or late systole, rises to a crescendo at the second sound, and diminishes thereafter to end usually about mid-diastole The second sound is usually distinguishable in the midst

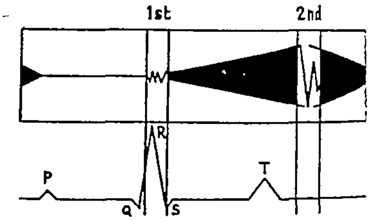

Fig 1—Phonocardiogram of typical murmur in a case arteriosus second left intercostal spac

of this murmur both by auscultation and b cardiography

The continuous hum of venous origin is mistaken for a ductus murmur, because it softer, and though more commonly right-sided heard up towards one or both clavicles an them It cannot be heard posteriorly, an unique in that it can be made to alter or to by turning the head or by digital pressure on in the neck

In cases of pulmonary atresia or persistent arteriosus the lungs may derive their blood-sup the aorta The anastomosis thus formed betw bronchial and the pulmonary vessels produce tinuous murmur This may be heard over an the chest Its point of maximal intensity is di locate but is not uncommonly posterior or in th It is usually a soft sound, uninfluenced by po or by venous pressure

Much less often the continuous murmur may over an arteriovenous aneurysm In anomaly is invariably congenital and may be The murmur may be heard in the axilla (Lu or over the aneurysm Equally unusual is the co

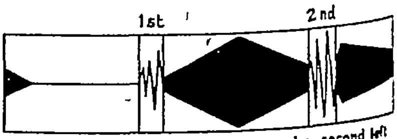

Fig 2—Outline of phonocardiogram in case 1 : second left space.

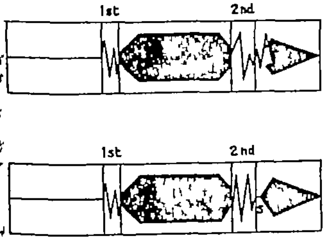
aortopulmonary communication, in which the audible over the base

The last two possibilities are even more rare foration of a sinus of Valsalva (aortic sinus) pulmonary artery or into the right ventricle by Wood (1950) as a cause of a continuous and (2) Taussig (1947) has heard such a murm case of congenital pulmonary stenosis and inco with associated anomalies of the aortic valves.

To this list must now be added the present Clinically these cases presented features strongly suggested patent ductus that thoracot done on four children, and a fifth died sudden he could be operated on Table II shows how the findings in these cases resembled those of a lductus, and in case 4 alone were there any ble grounds for doubt in this instance the d pulse-pressure were normal, and there was no rdiographic evidence of left ventricular hyper A normal electrocardiogram is commonly found of patent ductus, particularly in younger children 4, however, it is rather surprising in view of the cardiac enlargement

w of this difficulty in diagnosis to resolve which ory thoracotomy was undertaken an explanation e continuous murmurs should be sought In basal systolic and early diastolic murmur would uced by the aortic stenosis and incompetence ere originally diagnosed In the phonocardiogram nboid systolic outline of such a valvular stenosis ends about 0 04 sec. before the second sound continuity is present (Reinhold and Nadas 1954) tolic murmur of a ventricular septal defect (also in case 1) continues up to the second sound in ses It is conceivable that the superimposition sounds, together with those produced by fenes of the pulmonary valve cusps, would produce a indistinguishable from the continuous ductus on auscultation The phonocardiographic outline a combined sound might however differ slightly at of the ductus and in fact did so in case 1 sing a decrease of intensity of the murmur just he second heart sound The difference between ical patent-ductus murmur and the outline d in case 1 can be appreciated on comparing



asal diastolic murmurs: above silent period lost owing to of second component of second sound; below S indicates period.

and 2 This atypical outline has been observed r cases of patent ductus by Reinhold and Nadas but such an atypical tracing in cases with unusual features might be of some diagnostic value

2 is less easy to explain Endocardial fibro-elastic ing in the absence of damage to the valves, s no murmurs The ventricular septal defect be responsible for a long basal systolic murmur mid diastolic or even presystolic murmur at the but these could not produce a basal continuous

The other possibility is that the septal defect lmonary hypertension had enlarged the pulmonary o the extent of producing an incompetence murmur area Dilatation of the valve ring was found ortem. The trouble with this suggestion however, although murmurs due to incompetence heard at e are often early there may be a short silent period e second sound Wells et al (1949a) found that uarters of the basal diastolic murmurs had a cres liminuendo configuration (fig 3) but that a pure endo pattern is sometimes seen when the second nent of the second sound is delayed Whether t that most of the cases reported by Wells et al and b) were rheumatic in origin and not con is important or not it is impossible to say; but diastolic element in case 2 was due to pulmonary

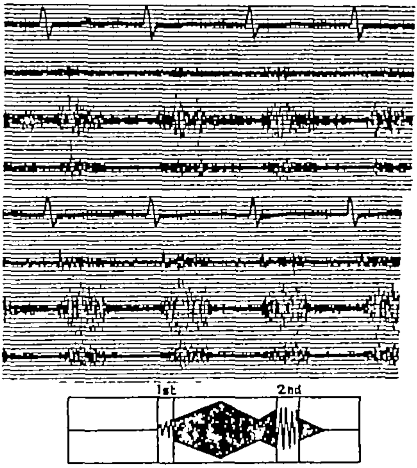


Fig. 4—Phonocardiogram in case 2: upper tracings second left intercostal space lower tracings, second right intercostal space.

insufficiency this case would have to be one of the 25% with pure diminuendo diastolic patterns (fig 3) The phonocardiogram of case 2 (fig 4) shows a rhomboid systolic configuration Although such a pattern is usually seen in valvular stenosis (see case 1) it has rarely been observed in cases of ventricular septal defect The continuous tracing is more obvious in the aortic area (see also case 5)

Case 3 is as difficult to explain The murmurs of aortic stenosis and coarctation could not produce a continuous sound over the base Precordial diastolic murmurs are sometimes heard in cases of coarctation of the aorta, but they resemble aortic insufficiency murmurs (Wells et al 1949b) These workers report the following interesting finding in six out of fifteen cases of coarctation "The diastolic vibrations were characteristically of decrescendo configuration being a continuation from the systolic murmur" This finding however was only observed when listening and taking tracings over the spine Mitral stenosis found post mortem in case 3 again raises the question of pulmonary incompetence as

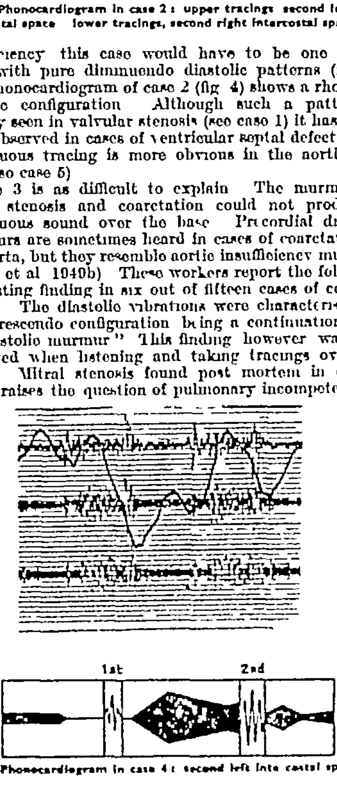

Fig 5—Phonocardiogram in case 4: second left intercostal space.

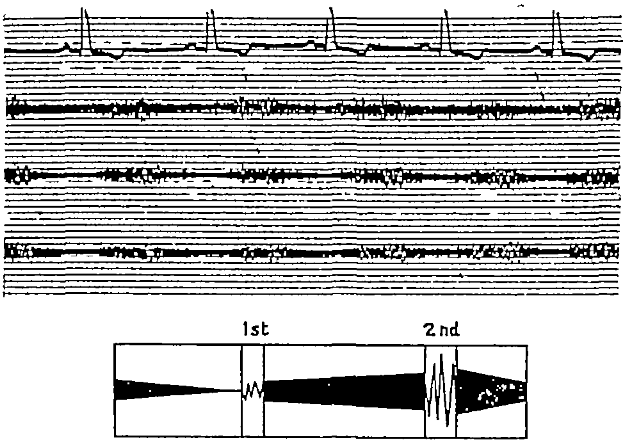

Fig 6—Phonocardiogram in case 5 second left intercostal space

a source of diastolic sounds, but much the most important alternative cause was a greatly dilated collateral internal mammary artery A continuous murmur is not infrequently heard on auscultation of the lactating breast, and it is known that the blood-flow through the internal mammary artery is greatly increased at such times Unfortunately no phonocardiogram could be taken from this child, because of the severe and persistent accompaniments in his chest

To explain the murmur in case 4 one must again assume that pulmonary incompetence produced an early diastolic murmur, and in this instance there is the suggestion of a short silent period (fig 5) The ventricular septal defect was proved by cardiac catheterisation and was doubtless responsible for the systolic element of the continuous murmur The complete outline (fig 5) was again atypical, showing much the same systolic outline as in cases 1 and 2

Case 5 closely resembles the first from the point of view of the phonocardiogram taken over the pulmonary area Fig 6 shows the aortic area tracing, which is quite typical of that of a patent ductus murmur Perhaps more importance should have been attached to this rather unusual finding Although the ductus murmur can often be heard to the right of the sternum, it is loudest (except in dextrocardia and cases of right aortic arch) to the left of the midline The finding of a high oxygen saturation in a high right ventricular sample on catheterisation might avoid the wrong diagnosis made in case 5 Although this finding would support the diagnosis of a ventricular septal defect it has been found in cases of patent ductus in which there is pulmonary regurgitation

The lesions detected clinically and post mortem are outlined in table III All the cases have multiple abnormalities, but a ventricular septal defect is common to all except one The cause of the murmur in this one exception might be the large internal mammary artery One is therefore probably justified in adding two further causes of continuous murmurs to those listed above complicated ventricular septal defect, and large tortuous collateral vessels

## Conclusion and Summary

An attempt has been made to explain a continuous murmur heard at the base in five cases of congenital heart disease None of these had the lesions which are recognised as causing such murmurs, and there is no way of further proving the accuracy of the explanations given It can be said, however, that in any case showing the features of a patent ductus arteriosus, and in which multiple lesions are suspected, a careful study of the phonocardiogram may be of some help In such cases causes of continuous murmurs should be born in mind complicated ventricular septal large tortuous collateral vessels

Intravenous angiocardiography does not al an answer and has its risks The greater ris grade aortography make it hardly justified at It is therefore likely that, in such difficult plicated cases as these, exploratory thor sometimes be done no matter how carefully are investigated Although the death rate is hi small series, it is considered that thorac has a relatively low risk, and that no ailin this type should be allowed to die without that the abnormality is not one which can be surgically

We wish to thank Dr J D L Reinhold for his advice about the phonocardiography, Mr D J F for the operations, Dr Martin Bodian and for necropsy and biopsy reports, Mr G H Bryant Robert for their technical assistance, and Mr D S the photographs

# HUMAN INFECTION WITH PLEUROPNEUMONIA-LIKE ORGAN

E Joan Stokes
M B Lond, M.R C P
BACTERIOLOGIST, UNIVERSITY COLLEGE HOSPITAL,

Although pleuropneumonia like organisms are well recognised animal pathogens, there vincing evidence that strains isolated from human disease (Nicol and Edward 1953) The animal susceptible to human strains makes pathogenicity by the application of Koch's impossible, but from the evidence set out below clear that, given suitable conditions, at least these organisms can cause severe illness

## Methods

Methods of isolation described by Edward (1 adapted for routine use

### *Media*

Since a suitable medium may be required and at short notice, it is important to use one already in use for some other purpose and is available in a fresh condition Human genital grow on defibrinated horse blood (10%) nutr after three or four days' incubation at 37 C, that the medium is fresh and remains moist strains so far found are aerobes but grow anaerobically In routine cultures growth better on the anaerobic plate because the atmo the jar is moist Aerobic plate cultures should incubated in small tins with an open tube water or sealed to prevent evaporation

Nagler's medium used for the rapid identific *Clostridium welchii* (Hayward 1941) supports of these microbes better than does blood agar improved for their isolation, without impa usefulness for other purposes, by reducing centration of agar so that the medium is sufficiently solid for handling in a petri dish P P L O are sought, the medium should be flo penicillin solution 10,000 units per ml or eryt solution 100 µg per ml., and the excess fluid tely before inoculation If thallium acetate final dilution is incorporated in the medium, the s can be isolated from discharges contaminated anisms resistant to penicillin and erythromycin medium is then unsuitable for any other purpose bs are allowed to dry before cultures are made it nely unlikely that P.P.L.O will survive The f swabs in the medium as described by Moffett 48) for the transport of gonococci has proved ccessful One strain survived on a swab in this for four days at room temperature

'Liquoid' broth method of von Haebler and 38) is suitable for the isolation of P P L O from d The blood broth cultures should be sub on both blood agar and Nagler's medium with a entration of agar *

### *tion for Growth*

es on blood agar and on Nagler's medium after ys incubation are very small only just visible ewed through a hand lens *in reflected light* ncubation does not increase their size They are nt and tend to embed themselves in the medium minute pits when they *are scraped off* This microbes and their differentiation from the of bacteria have been fully described by Edward The main difference between them and other rowing bacteria is their morphology If the are scraped from solid medium and gram in the usual way no recognisable structures will It is essential to examine them in an impression ion so that the colonies are not destroyed

ke an impression preparation, first sterilise a clean by flaming it When it is cool, press it gently on the f the medium over the suspected colonies and leave few seconds. Then lift it carefully off the medium eps, without sliding it on the surface so that the are not distorted Flame it again lightly to fix the ion and place it colonies uppermost on a glass slide the slide with paraffin wax for convenient handling by Gram's method

olonies are gram negative and have a sponge like nce with minute bacilliform and coccoid bodies at phery They are quite unlike other bacterial examined in the same way Giemsa and n stains show their structure rather better am's stain does

microbes are not easily recognisable in liquid either in stained preparations under dark illumination or by phase-contrast microscopy dium containing cells it is difficult to distinguish om the products of cell degeneration In smears ed discharges they are unrecognisable Expert handling them can be gained by culturing cervical ginal swabs from patients attending venereal clinics About 70–80% positive results can be l (Nicol and Edward 1953)

### *ic Analysis*

ccessful attempts were made to prepare aggluti antigen by centrifuging liquid cultures and by the growth from the surface of solid medium tory suspensions were sometimes obtained but ot be relied on Serological tests were therefore complement fixation only using Belyavin's modification of Fulton and Dumbell's micro o It was found that a 'chess board' titration d by Belyavin for influenza virus complement was not required because the highest con on of antigen was always the most active No s were seen

ens were prepared by centrifuging 4–5 day human (10%) broth cultures at 3000 r p m for at least one hour and resuspending the deposit from 100 ml in 4 ml of saline solution Drops of the supernatant fluid seeded on Nagler's medium yielded a semiconfluent growth and it was found that the activity of the antigen could be increased about fourfold by more efficient *centrifugation at 14 000 r p m for 30 minutes* Killing the organism by heat at 56°C rendered the suspension anticomplementary the antigen used, therefore, was an untreated living saline suspension

COMPLEMENT FIXING ANTIBODY TITRES IN HUMAN SERA (EXPRESSED AS FINAL DILUTION OF SERUM)

| Case no | *Homologous antigen* | Time after onset of symptoms | | | | |
|---|---|---|---|---|---|---|
| | | 0–10 days | From 14 days to 1 month | 1–2 mos | 2–3 mos | 6 mos |
| 1 | 1345/51 | | | 12 | 6 | < 3 |
| 2 | 8007/53 | < 3 | 480 | 120 | 12 | 3 |
| 3 | 1780*/53 | < 3 | 40 | 240 | | 21 |
| 4 | 2131/53 | < 3 | 48 | 24 | | < 3 |

Antigens for injection into rabbits for the preparation of specific antisera were also concentrated living suspensions similarly prepared but the strains were cultured in 10% rabbit-serum broth Material for the final injection was centrifuged at high speed (14 000 r p m for 30 minutes) Rabbits were injected intravenously on days 1 2 4 6 8 and 9 They received on each occasion the deposit from 90 ml of fresh 4–5 day culture A titre of complement fixing antibody of about 2880 could be expected on the 14th day It began to fall 14 days later—i e a month after the first injection The rabbits showed no sign of illness

## Clinical Records

**Case 1**—A woman aged 43 was delivered of her first child on Jan 13 1951 The delivery was difficult and performed with forceps On the second day of the puerperium, while receiving sulphonamide she developed pyrexia (103 F) Soluble penicillin 1 mega unit followed by procaine penicillin 300 000 units twice daily had no effect on the temperature which continued to swing between 99 and 103 F during two days treatment which was then discontinued

*Investigations* made on the fifth day after delivery gave the following results. Blood-cultures (in air in air plus 5–10% carbon dioxide and anaerobic) yielded a pure growth of P P L O on the tenth day of incubation Microscopy of the urine showed 8 pus cells per 1/4 inch field a culture (blood agar aerobic 1 day at 37 C) was sterile A high vaginal swab contained degenerate pus cells gram negative bacilli, and gram positive cocci and on culture (blood agar 2 days at 37 C) yielded a fairly heavy growth of *Escherichia coli* and anaerobic fusiform bacilli A white-cell count showed 13 000 per c.mm. (polymorphs 98%)

*Treatment*—On the sixth day although the blood-culture result was not yet known the patient was given aureomycin. Her temperature immediately began to fall and was normal by the end of the eighth day She was discharged fit on the twenty sixth day after an investigation for renal disease which proved negative Samples of serum were collected to be examined for antibodies against the organism isolated from her blood (see table)

The titres recorded from case 1 are low in relation to the severity of her illness but this is not surprising because when they were estimated experience had not been gained in the preparation of antigens and in the light of later work probably only a high titre serum would have reacted at all with the crude antigen then used Unfortunately when a satisfactory antigen became available the sera were unsuitable for further tests

**Case 2**—A girl, aged 1 with bronchiectasis was admitted in April 1953 for removal of the basal segments of the lower lobe of her right lung Treatment with penicillin 250 000 units six hourly was started the day before operation The day after operation the patient developed a small bronchopleural fistula, which was closed on the evening of the same day, penicillin being introduced into the wound On the sixth day her general condition was improving Her temperature had ranged between 100° and 101°F since the operation. On the seventh day a drainage tube was removed from the wound, and six hours later the patient had a rigor, and her temperature rose to 103°F and remained high and swinging for five days

---

* of these methods are also to be found in my *Clinical* ology London 1955

*Investigations*—A blood count showed 14,000 white cells per c mm (polymorphs 80%) and radiographs of the chest revealed fluid in the right pleural cavity Blood cultures in air, in air plus 5–10% carbon dioxide, and anaerobic were sterile during three weeks' incubation A swab taken from the wound shortly after the rigor yielded a pure growth of P P L O Fluid aspirated from the pleural cavity five days later also yielded a pure growth of this organism, which was resistant to penicillin and sensitive to aureomycin.

*Aureomycin treatment* was followed by clinical improvement, and the temperature fell to 100°F three days later Fluid aspirated from the chest after five days' aureomycin treatment showed numerous pus cells, but the cultures were sterile On the following day a rib was resected to drain the empyema, after which the child made an uninterrupted recovery and was discharged healed nine weeks after the original operation The results of tests for P P L O antibodies on several samples of serum are seen in the table

**Case 3**—A married woman, aged 31, undergoing investigation for sterility was admitted on Sept 3, 1953, acutely ill with abdominal pain and fever She had a long history of abdominal sepsis At the age of 16 she had been in hospital for three months after appendicectomy In 1946 she was operated on for bilateral tubo ovarian abscesses The investigation for sterility had revealed a right hydrosalpinx, and twelve days before admission her fallopian tubes had been radiographed

*On admission* her temperature was 103°F, and investigations gave the following results A high vaginal swab contained numerous pus cells and mixed organisms, and on culture (blood agar 2 days at 37°C) yielded a heavy growth of anaerobic streptococci A white cell count showed 14,700 per c mm (polymorphs 77 5%) No abnormality was found in the urine

*Treatment* with penicillin and sulphonamide for two days produced no effect On the third day a second swab was cultured and streptomycin was given A high vaginal swab contained numerous pus cells but no microbes, and on culture (blood agar aerobic and anaerobic 3 days at 37°C) yielded a heavy growth of P.P L O and a scanty growth of *Esch coli* On the fourth day treatment was changed to aureomycin, after which the temperature never rose above 101°F and the patient's general condition improved On the eighth day a large right tubal abscess was aspirated per vaginam No microbes were seen in the smear of the pus, and cultures yielded a heavy growth of P.P L O and a few colonies of *Esch coli* Colpotomy was done on the ninth day and was followed by an uneventful recovery Results of serological tests are shown in the table

**Case 4**—A married woman, aged 24, was delivered of her second child on Nov 24, 1953, at home She was rescued from a severe postpartum hæmorrhage by the "flying squad" and was admitted to the hospital the same night No antibiotics were given Three days later the patient was well, apart from slight persistent pyrexia (99°–100°F)

*Investigations* gave the following results A high vaginal swab contained moderate numbers of pus cells but no microbes, and on culture (blood agar aerobic and anaerobic 3 days at 37°C) yielded a pure growth of P P.L.O No abnormality was found in the urine The fever subsided on the eleventh day of the puerperium without antibiotic treatment A second high vaginal swab, taken fifteen days after delivery, showed fairly numerous epithelial cells and a few pus cells, and on culture yielded a scanty mixed growth No P.P.L.O were isolated The results of serological tests are shown in the table

## Controls

Of 172 sera tested 171 were negative—i e, they gave titres less than 3 They comprised the following

107 sera sent for Wassermann reaction and found negative

34 from patients with acute respiratory infections (sera taken between tenth and thirty fourth days after onset and ation for virus antibodies)

1 primary atypical pneumonia, second week,
tinin and streptococcus M G agglutinin positive.

19 from women six weeks after childbirth.

5 from pregnant women

1 gonococcal arthritis (gonococcal compl
test positive)

1 arthritis (gonococcal complement fixation tes

2 Bartholin's abscess with less than a week's h

1 abdominal abscess with 2 week's history

One serum from a patient with a six days'
Bartholin's abscess and a positive gonococcal co
fixation test (titre 24) gave a P P L O titre of
abscess opened spontaneously, and the pus
cultured The patient had had a similar abs
three months previously, and the pus showed no
in the smear and on culture yielded no signific
unfortunately one of the plates was con
Selective medium for P P.L O was not used. Th
is still under investigation

Positive reactions with the sera of
uninfected patients, which were observed by
et al (1946) in their serological investigation
specific urethritis, were not seen in the presen
gation Their complement fixation method had
successful in testing the sera of cattle with c
bovine pleuropneumonia Possibly, however, t
gen was not suitable for testing human sera
although the strains used were of human
medium in which they were cultured conta
ox serum, which during extraction of the an
have given rise to some non specific substance
reacting with human serum

The strain isolated from the blood has been
by Dr D G ff Edward, who classifies it with th
type 1 genital strains (Edward 1954) The othe
appear to be culturally and serologically simil

## Bacteriology

All four strains are aerobes and showed
colonies on moist fresh defibrinated horse bl
after three days' incubation at 37°C on first
Further incubation did not increase the size of th
which dried up and finally disappeared. Th
maintained until April, 1954—i e, from four
three years—by subculture twice weekly on F
(5%), human serum or plasma (20%), and
agar † without protection by antibiotics or oth
inhibitors Their morphology and cultural
teristics remained constant, and there was no
reversion to a normal bacterial form They
maintained on a selective medium to lessen th
contamination They are all sensitive to
oxytetracycline, and chloramphenicol, moderate
tive to streptomycin, and resistant to pen
erythromycin

All four strains from these patients and th
isolated in mixed culture from the cervix o
attending the venereal disease clinic appear
serologically homologous when tested against
human sera or the specific rabbit sera High
sera inhibited their growth (Edward 1950),
effect was not seen with the comparatively
human sera

## Discussion

These four patients all showed a clinical p
infection Culture of appropriate specimen
conditions suitable for the growth of aerobic and a
pyogenic bacteria yielded a heavy growth of
and no other cause for the symptoms could b
In three of the cases recovery followed treat
aureomycin, to which the strains were sensiti

---

† Nagler's medium for the identification of Cl welch
1941)

atment had failed In two cases the microbe t be isolated from the original site of infection atment with aureomycin Finally in three of ents specific antibody developed during the reached a maximal titre at about three weeks onvalescence, and fell thereafter No antibody d in sera from uninfected patients or in the sera its with other infections

is therefore good evidence that the P P L O from these patients were responsible for the symptoms It might, however be argued that ier pathogen had been killed by antibiotic treat fore the specimens were taken This does not case 4, who received no antibiotics and seems in the other cases, since there was no clinical ment until an antibiotic effective against P P L O l Primary infection by a virus could be postu ut a purulent exudate present in three of these not a feature of the virus infections so far recog Symbiotic infection with a virus cannot be but in the absence of evidence such an ion seems needlessly complex

is particularly interesting because even though tion was clinically very mild and was followed taneous recovery specific antibodies developed. was not very high but the gonococcal comple ation test often yields titres which are no higher ch are nevertheless accepted as of diagnostic ace

rological findings in the cases reported indicate complement fixation test may be useful in the ation of non specific urethritis and venereal Consistently negative results in tests of of serum obtained from patients at suitable against pathogenic human genital strains of would make it very improbable that such is were responsible for the clinical condition ion of the test does not require the maintenance cultures of the organism, for a freeze-dried ion of antigen remains suitable for at least nine

## Summary

cases of human infection with P P.L.O are d: two of puerperal sepsis one pyosalpinx and stoperative empyema Methods of preparing for serological diagnosis and for the isolation of microbes from infected discharges are briefly d

ssion preparations are essential for the micro examination of colonies

media must remain moist during three or four cubation

material examined must be fresh or taken on a d placed in transport medium

en suitable for human serological diagnosis by ent fixation is a concentrated living suspension organism

to thank Prof Wilson Smith for his encouragement re throughout this investigation, and his technical help in the preparation of antigens; Dr I M for isolating the strain from case 1 and for main he cultures for several months; Dr F F Bowers for the strain from case 4; Dr F O MacCallum for serum from cases of respiratory infection Dr Edward for examining strain 1346; and Mr J D S rof R S Pilcher and Prof W C W Nixon for on to publish their cases.

# ŒSOPHAGEAL REFLUX

B Creamer
M.D Lond. M.R C.P
LECTURER IN MEDICINE, ST THOMAS'S HOSPITAL MEDICAL SCHOOL, LONDON

Œsophageal reflux has received much attention from radiologists and surgeons so its incidence and clinical features are well known but the conditions under which the cardia becomes incompetent except the common association with hiatus hernia have remained obscure

In the investigation described here the intra-œsophageal and intragastric pressures were measured in an attempt to define the changes accompanying reflux and to find if any constant pattern of events precipitated reflux

## Methods

The pressures were measured through fine 'Polythene tubes with Hansen capacitance manometers (Dornhorst et al 1954) In most experiments three tubes were used together joined at the tip and recording through lateral holes usually 5 cm apart The tubes were filled with water and the distal parts beyond the recording holes were filled with mercury which enabled the exact position of the recording holes to be localised by radiography The respiratory movements were simultaneously recorded by pneumography

Twelve cases of œsophageal reflux were investigated, in four of these the cardia was in the normal position, determined by barium studies and in eight a hiatus hernia was present Twelve cases with normal function of the cardia were studied as controls

## Results

### *Recognition of Reflux from Pressure Changes*

A pressure change due to œsophageal reflux could be detected In two cases simultaneous screening of the patient after drinking a barium emulsion confirmed the relation between the pressure change and the radiological appearance of reflux Superimposed on the normal respiratory pressure-swing a positive pressure-wave about 5 mm. Hg passed very rapidly up the œsophagus (fig 1) This wave lasted 1–2 sec and was a simple peak in shape often leaving the œsophageal pressure at a slightly higher level than before until the refluxed substance was expelled from the œsophagus In this latter respect it resembled the initial rise in pressure in the œsophagus

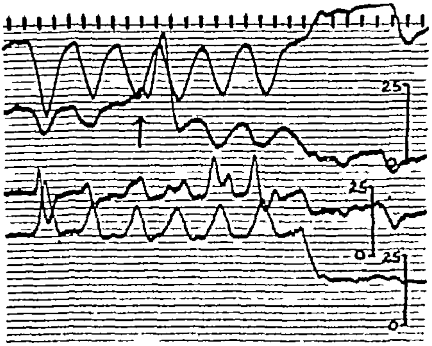

Fig 1—Recording from patient with normal position of the cardia leaning forward in bed. Top tracing: pneumogram (inspiration downwards) Lower three tracings are recordings from tubes 5 cm. apart: top tube in œsophagus; middle tube at cardia; lowest tube in stomach. Arrow indicates reflux Initiating propulsive wave At the end of the recording the patient changes position (see fig 2)

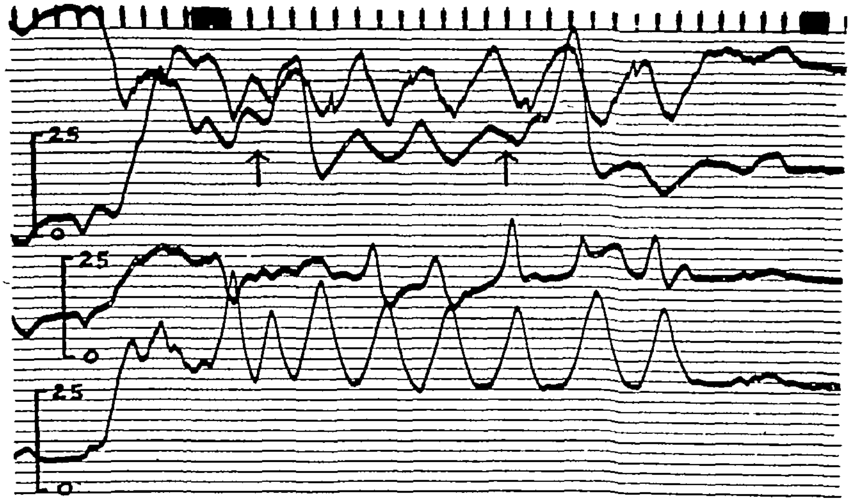

Fig 2—Recording from same patient as fig 1 leaning forward at beginning of recording Top tracing : pneumogram (inspiration downwards) Other tracings as in fig 1 Arrows indicate reflux shown in œsophageal tracing by diminished fall in pressure with inspiration followed by propulsive waves Final signal at top of record marks onset of heartburn

on swallowing Similar pressure waves were seen whether the substance refluxed was fluid or gas In cases where gas was refluxed the positive pressure wave appeared simultaneously in all parts of the œsophagus Where the substance refluxed was fluid the pressure-wave was sometimes limited to the lower œsophagus and sometimes diminished in height as it progressed upwards No general rise in intragastric pressure near the cardia preceded reflux, and the shape of the wave and the rapidity of its passage showed clearly that this was due entirely to the entry of gastric contents into the œsophagus and not to reverse peristalsis Reverse peristalsis has never been observed in any case of œsophageal reflux and only in one patient who had a postoperative stricture at the lower end of the œsophagus Instead of the positive wave there may be only a failure of the intra œsophageal pressure to drop with inspiration, but this seems to be less common (fig 2)

*Œsophageal Reaction to Reflux*

When gastric fluid appeared in the œsophagus, a propulsive wave was often initiated which progressed normally to the cardia, leaving the intra œsophageal pressure at a normal level (fig 1) This wave seemed to be caused by the presence of fluid in the œsophagus, because it could be provoked by injecting water through a tube into the œsophagus Following the pressure changes of gas reflux the pressure in all parts of the œsophagus usually rose simultaneously and eructation occurred In patients with the symptoms of œsophagitis reflux sometimes initiated uncoordinated contractions, many of which seemed to be localised and did not proceed normally cardia Œsophageal within 30 sec. after the gastric fluid into the was not related to the contractions (fig 2)

*Conditions Predisposing*

A reflux wave occur ing inspiration Further reflex was present at beginning of inspiration reflux wave rose with the increase in pressure Reflux did not every inspiration and times intermittent (fig

Reflux occurred more in some positions than was most often found patient leaning forward in bed, and after this patient supine Small the patient's posture caused reflux The

ence across the cardia was measured in by withdrawing a recording tube from the the œsophagus (fig 3) The pressure difference

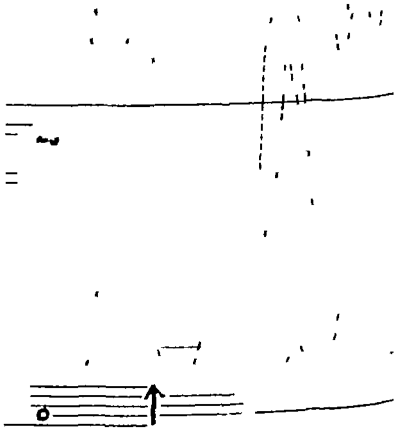

Fig 4—Recording from patient with hiatus hernia and tracing pneumogram (inspiration downwards) tracings are recordings from tubes 5 cm apart in œsophagus bottom tube in hernia. At start of changes position slightly and then reflux occurs initiates propulsive wave. Note similarity of to that of normal intragastric pressure

only 1–2 mm Hg in all positions from lying toe-touching and was about In positions, such as where the abdomen is the intragastric and intra- pressures about the together

*Pressures in Hiatus Hernia*

The observations listed collected mainly from patient the cardia was in the norm Similar results were obt patients with hiatus hern Pressure recordings from within a hernia often showed from the usual respiratory swing recorded in the œsoph common pattern was a bi

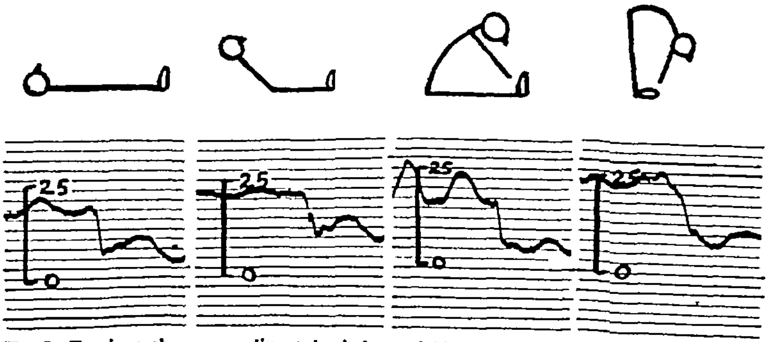

Fig 3—Tracings show recording tube being quickly withdrawn from stomach to œsophagus in different positions Note that pressure difference during expiration varies mm Hg

th inspiration (fig 5) though occasionally rn closely followed that of the intragastric swing (fig 4) It was shown in these cases cardia was not incompetent the whole time ing tube at the cardia showed with inspiration l rise of pressure followed by a fall as the ig diaphragm pulled the closed cardia over the hen the cardia was open this pattern was altered pressure did not fall

### Discussion

these observations on pressure changes the facts about œsophageal reflux become apparent

s possible to recognise reflux as a positive pressure he œsophagus and less often by a diminished drop sophageal pressure during inspiration

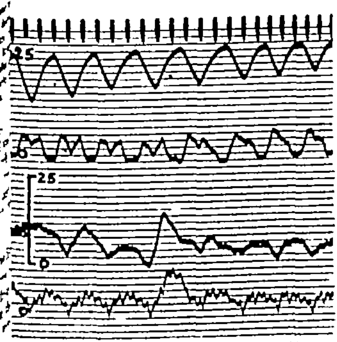
lux takes place only during inspiration

lux takes place in some positions more commonly rs, and small changes in posture may render the ompetent

se changes in posture are not accompanied by any ble change in the pressure gradient across the cardia

tructures forming the cardia are mobile and in their relative positions are easily induced by n of posture This can be seen from routine neal radiographs Probably in patients with eal reflux the competence of the cardia depends lative anatomical shape The association with on is interpreted as positional, the descending m flattening the fundus of the stomach There idence of a pressure change forcing the cardia of reverse peristalsis Dornhorst et al (1954) examining the normal cardia at operation nder it incompetent only by manipulating the o that it formed an obtuse angle with œsophagus. orkers have shown that the cardia acts as a valve ulate that it is formed by the lax gastric mucosa rea. The above mentioned observations fit well s conception because changes in the shape of ia must be reflected by changes in the tensions ucosa.

ct that reflux takes place solely with inspiration r evidence that the right crus of the diaphragm part in maintaining the competence of the cardia, its effect should be maximal during this time method of detecting œsophageal reflux may be because it is well known that reflux may be to demonstrate radiologically in cases where the diagnosis is reasonably certain.



ecording from patient with hiatus hernia. Upper tracing : gram (inspiration downwards) Lower three tracings are ges from tubes 5 cm. apart : top tube in hernia ; lower two hagus. This is reverse of positions in figs. 1 2 and 4. Note ttern of respiratory pressure-swing from hernia.

### Summary

Œsophageal reflux is accompanied by pressure changes in the intra œsophageal pressure which can be used to detect its occurrence

Reflux takes place only during inspiration and more commonly in certain positions of the patient than in others There is no appreciable change in the pressure gradient across the cardia in these positions and it is postulated that the competence of the cardia depends on its anatomical shape

No evidence was found of reverse peristalsis and the observed facts fit well with the conception of a mucosal valve guarding the cardia

I wish to thank Dr A C Dornhorst for help and encouragement during this investigation and Mr R W Halls and Mr M G Ventom for technical assistance

# APLASTIC ANÆMIA FOLLOWING MEPACRINE TREATMENT OF LUPUS ERYTHEMATOSUS

M D Paton
M B Edin.
HOUSE PHYSICIAN

M. J Piddell
M D Lond M R C P
SENIOR REGISTRAR

J A Strong
M.B.E M B Dubl M R C P
PHYSICIAN

WESTERN GENERAL HOSPITAL, EDINBURGH

The earliest reference to the treatment of lupus erythematosus with mepacrine appears to be that by Popoff and Kutintscheff (1943) who recorded the successful treatment of 6 patients Page (1951) reported a series of 18 patients in many of whom the drug controlled the lesion and this form of treatment is now firmly established

The toxic effects have included blood dyscrasia Apra (1953) described leucopenia and Wilkinson (1954) agranulocytosis Vilanova and de Moragas (1953) reported 1 death from agranulocytosis Sawicky et al (1952) and Parmer and Sawitsky (1953) each noted 1 fatal case of aplastic anæmia in patients with lupus erythematosus who had been treated with mepacrine A further such case is reported here

### Case report

A woman farm worker aged 53 had had chronic discoid lupus erythematosus for some years and in 1952 she was successfully treated with mepacrine hydrochloride 100 mg t.d.s Thereafter she took intermittent courses of mepacrine in this dosage In February 1954 because of a relapse in her skin condition she again started to take mepacrine hydrochloride 100 mg t d.s. and continued until she had taken about 200 tablets (20 g ) In early May a fortnight before admission, she stopped taking the drug and then noticed two large bruises which had appeared without apparent preceding trauma. Thereafter bruises appeared at short intervals, and later purpuric spots, especially on the legs followed by melæna and hæmatemesis. Her consumption of foods containing ascorbic acid had been low and her doctor had prescribed tab ascorbic acid 50 mg t d.s on the day before admission There was no family history of a bleeding diathesis.

*Examination* —The patch of lupus erythematosus was scarcely discernible as a faintly pigmented area on the left cheek. The skin of the face forearms and legs was conspicuously yellow There were numerous petechiæ on the trunk and limbs together with many ecchymoses of varying age and size some as large as 2 in. in diameter No enlargement of lymph glands was found Systematic examination showed no other relevant abnormality

*Investigations*—Urine, normal  Blood  Hb 64% (Haldane), red cells 3,150,000 per c.mm, white cells 1900 per c mm (neutrophils 24%, lymphocytes 76%), platelets 70,000 per c.mm, clotting-time 7 min, bleeding time over 80 min, Hess test positive, erythrocyte sedimentation rate 118 mm in 1st hr (modified Westergren)  Serum bilirubin 0 5 mg per 100 ml  Plasma proteins 5 7 g per 100 ml (albumin 4 2, globulin 1 5)  Cephalin cholesterol flocculation test negative  Alkaline phosphatase 9 King Armstrong units  Prothrombin concentration 100%  Ascorbic acid saturation test (700 mg given daily by mouth) urinary output 11 mg on 1st day and 66 mg on 2nd day

*Progress*—On the day after admission, blood examination showed Hb 29% (alkaline hæmatin) (4 4 g per 100 ml), red cells 1,380,000 per c mm, packed cell volume 13%, mean corpuscular volume 94 c µ, mean corpuscular hæmoglobin concentration 34%, white cells 2600 per c.mm (neutrophils 29%, lymphocytes 70 5%, monocytes 0 5%), platelets 25,000 per c mm, bleeding time over 60 min, coagulation time (capillary tube) 2½ min  Sternal puncture showed a few scattered, damaged marrow cells, on which a definite opinion could not be passed

After transfusion of three bottles of blood (approximately 1500 ml) the hæmoglobin was 42% (Haldane)  The patient then became febrile, and despite treatment with penicillin and later erythromycin her condition deteriorated  Bullæ appeared on the trunk, and the hæmatological findings remained virtually unchanged  A course of corticotrophin (Armour) 80 units daily was given for 4 days, but she died in coma on the 11th day in hospital  Blood for culture taken 2 days before death proved sterile

*Necropsy*—The examination was made 19 hours after death  Advanced putrefactive changes were present, with swelling of the face, neck, and abdomen  The superficial veins were outlined in a dark red colour  The subcutaneous tissues were crepitant, and rigor mortis had passed off  Diffuse petechial hæmorrhages and ecchymoses were present with areas of superficial desquamation some ulcerated  Internally, the only distinct lesions were petechial hæmorrhages in the subepicardial fat and throughout the mucosa of the whole intestinal tract  The marrow of the mid shaft of the femur showed no evidence of reactive hyperplasia

Microscopically, all organs had been invaded by *Clostridium welchii*  Sections from the bullous areas showed a superficial line of separation in the epidermis, in or just below the keratin layer  No polymorph reaction was present in the blister fluid or deeper layers, and no inflammatory reaction at the buttock ulcer—a former injection site  There were no changes suggesting lupus erythematosus in the renal glomeruli

Bone marrow (vertebral) showed a few small scattered foci of hæmopoietic cells, which, owing to putrefactive changes, could not be identified  The appearance was consistent with marrow aplasia

### Discussion

Custer (1946) found 57 fatal cases of aplastic anæmia among Servicemen in the South-West Pacific theatre, where the vast majority took suppressive doses of mepacrine (100 mg daily)  In other war theatres the incidence of aplastic anæmia in the Services was, by comparison, insignificant

Fishman and Kinsman (1949) described 7 military patients who had been on suppressive treatment with mepacrine and developed hypoplastic anæmia, 3 of these eventually died  Bruce Chwatt and Bruce Chwatt (1950) and Riesgo (1951) reported similar fatal cases

It would seem well to bear in mind the possibility of bone marrow damage in patients treated with mepacrine  Although agranulocytosis can occur without warning, by regular blood counts impending marrow aplasia might sometimes be recognised before irreparable damage had occurred  That this is possible is suggested by the experience of Fishman and Kinsman (1949)  Of their seven patients, four recovered

### Summary

Fatal aplastic anæmia is reported in a patient with localised lupus erythematosus who had been treated with mepacrine

The risk of marrow aplasia resulting from administration of mepacrine should be rem treating patients with lupus erythematosus

We are grateful to Dr J M Drennan for the p report

# MALIGNANT SENSORY NEUROP

W Thomas Smith
M B Birm
LECTURER IN PATHOLOGY, UNIVERSITY OF BIR

A G W Whitfield
M.D Birm, F.R C P
ASSISTANT PHYSICIAN, QUEEN ELIZABETH
BIRMINGHAM

It has been recognised for many years that disturbances are occasionally associated disease in the absence of any obvious meta ment of nervous tissues  Recorded cases, comparatively few, suffice to show that a of unusual neurological disorders accomp with a significant frequency" (Henson et Among these disorders subacute cortical degeneration (Brain et al 1951), proximal pathy (Hart 1954), and sensory Brown 1948) are separable as fairly distinct other less well defined clinicopathological from lesions involving virtually any part of and peripheral nervous systems and also m myopathy, mixed types of polyneuritis peripheral and cranial nerves, pyramidal and mental changes occur sometimes in almost but more often in varying combinations. H (1954) recently described five cases of cerebell six of neuropathy, and eight of myopathy, and and Williams (1954) two cases of sensory ne one of motor neuropathy, and one of myopath two reports demonstrate the diversity of ne disorders that may be associated with c Furthermore, purpuric states, venous throm baum and Strich 1953, Williams 1954), and carc emboli (Smith and Whitfield 1954) are ciated with carcinoma and may result in lesions responsible for the presenting clinical

Instances in which peripheral neuritis of dominantly sensory type was associated with carcinoma have been described by Parke Hill (1933), Denny Brown (1948), Wyburn Ma Kremer and Pratt (1952), Heathfield and Willi and Henson et al (1954), while Dodgson and (1953) recorded a case in which the primary gr œsophageal

The neuropathy has usually been gross and striking feature  Necropsy has shown demye the posterior columns and posterior nerve roots, tion of nerve cells in the posterior root gangli development of cellular nodules resembling the nodules of Nageotte" (Nageotte 1907), nerve degeneration, and some muscle atrophy

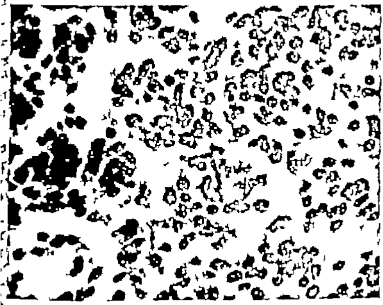
Gross neuropathy of wholly sensory type found, and there can be no doubt that in the diabetes and alcoholism malignant disea o be present, even though at first it may not to detect. A striking example of this type is below

## Case-report

ied woman aged 66 was first seen on June 16 195_ always been of nervous temperament but otherwise healthy until February 1952 She then developed of burning and smarting all over her abdomen and h legs. Her legs felt wooden and she could not walk her arms felt cold, and her fingers numb and weak weeks before she was first seen she had sustained a urn of the right foot which appeared to be [illegible] com ry strikingly little pain. Her consumption of alcohol at life had been negligible

*ation.*—The patient's gait was very ataxic and there of sense of position and of sensibility to deep pain rick over the legs and feet while the hands showed ensibility to vibration and pinprick The ankle right biceps jerk, and both triceps jerks were absent s no motor loss or wasting The hæmoglobin was there was no glycosuria the chest radiograph was d no abnormality could be detected in the abdomen

—The patient was treated with vitamin B complex ew of her failure to improve she was admitted to the lizabeth Hospital Birmingham, on Dec 27 1952 A efore admission she had sustained a further deep but burn of the right knee from sitting in front of the ere was still no motor loss or wasting in the limbs but ory polyneuritis was much more severe The gait was ataxic all the tendon jerks were absent in upper and limbs and there was pronounced impairment of all f sensation in the hands and forearms and the whole ower limbs Even over the trunk sensory acuity was at diminished. A blood-count was normal and a tal test meal showed abundant free acid The cerebro luid (C.S.F.) which was under normal pressure showed ormality on cytological and chemical examination. assermann reaction was negative in blood and C.S.F. e urine did not contain lead porphyrins, or arsenic tient had obviously lost a great deal of weight and so a search for malignant disease was again instituted A adiograph showed no abnormality; the breasts and were normal; radiography after a barium meal no abnormality in the alimentary tract nothing tal was found in the urine; and the fæces were negative ult blood A complaint of previous vaginal bleeding estigated by a gynæcologist Dilatation and curettage senile endometritis but no evidence of a pelvic m.



Anaplastic small-cell carcinoma of bronchus. (Hæmatoxylin and eosin.)

e patient's husband was dying of a pancreatic neoplasm t hospital after a month and was not seen again until 1953 She was then so ataxic that she could scarcely or walk Motor power in the upper and lower limbs d good; but all tendon jerks and the plantar responses bsent all forms of sensation were totally lost below guinal ligaments, and perception of pinprick and light were grossly impaired in the forearms and hands,

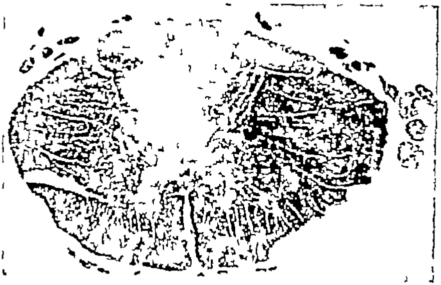


Fig 2—Cervical cord showing demyelination of posterior columns and posterior roots. The nick marks the right anterolateral column (Frozen section Weil's myelin method.)

particularly the left Blisters were present on both heels. Cough and sputum had been troubling the patient for two or three weeks and a large right pleural effusion was present which on aspiration was found to be bloodstained Radiography of the chest showed a mass in the right lower hilar area, and radiography with a barium swallow showed indentation of the œsophagus at the level of the tracheal bifurcation and again two inches below Auricular fibrillation was present. The patient's general condition was very poor and she became progressively more dyspnœic and died one week after admission eighteen months after the onset of neuritic symptoms.

*Necropsy*

A large carcinoma of the right lower lobe bronchus was infiltrating the lung substance and extending proximally along the bronchus towards the tracheal bifurcation There was a right pleural effusion of about three pints and a large mass of hilar lymph nodes containing secondary deposits was displacing the œsophagus anteriorly and infiltrating the posterior surface of the heart No other metastases were found on naked-eye examination anywhere in the body Ante-mortem thrombus was found in the ascending aorta and was adherent to the aortic valve The brain and spinal cord showed no significant naked-eye changes.

*Histologically* the bronchial growth was an anaplastic carcinoma composed of small darkly staining round and oval cells (fig 1) an oat-cell type of structure was seen in many areas Sections of lung remote from the carcinoma showed no infiltration. The hilar lymph nodes were extensively infiltrated with secondary growth, as was the whole thickness of the left auricular myocardium, carcinoma cells being present on the endocardial surface Partly necrotic cellular tissue resembling degenerating carcinoma was seen in the centre of the aortic thrombus, but no unequivocal non degenerate carcinoma was present Apart from interstitial

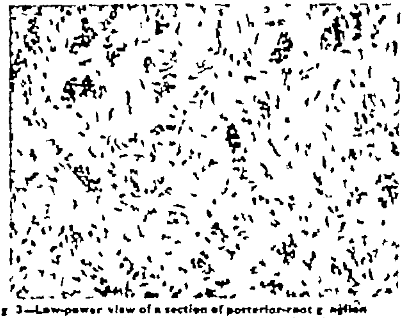

Fig 3—Low-power view of a section of posterior-root g [illegible] loss of neurones and numerous "residual nodules." [illegible] and eosin.)

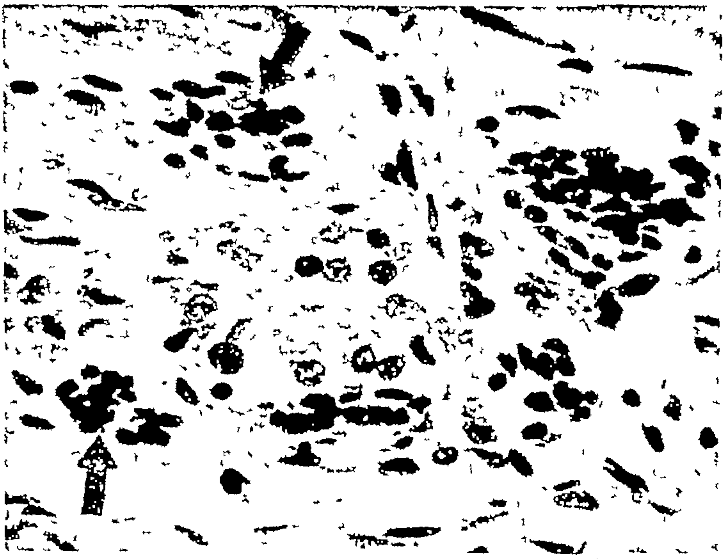

Fig 4—High-power view of posterior-root ganglion showing three adjacent "residual nodules" (arrowed) arranged around a degenerate ganglion cell which is in the centre of the field Note the smaller clusters of dark cells just below this degenerate ganglion cell (Hæmatoxylin and eosin)

fibrosis of the thyroid no other significant changes were seen in any other viscera, including the endocrine organs The bone marrow was normal

The spinal cord showed demyelination of the posterior columns with slight gliosis (fig 2) The posterior roots were demyelinated, but the anterior roots, anterior horns, and anterior and lateral columns, all appeared normal The posterior root ganglia showed a great reduction in the number of ganglion cells and numerous clumps of small cells with darkly staining round or oval nuclei and only a small amount of cytoplasm, some of these cellular clumps were ringed by larger, paler, capsular cells These resembled the "residual nodules of Nageotte" which are said to develop as a result of changes in the periganglionic satellite cells, after degeneration of ganglion cells which have disappeared by the time the nodules are fully developed (figs 3 and 4) Lipo fuscin pigment was demonstrated in relation to some of the nodules and in the few surviving ganglion cells by the periodic acid Schiff stain There was patchy wallerian degeneration of the peripheral nerves, and sections from the leg, lumbar, shoulder, and intercostal muscles showed non specific atrophic changes The only other changes in the nervous system consisted of occasional foci of small darkly staining cells in the cerebral perivascular spaces, subarachnoid space, posterior roots and ganglia, and the epidural fat around these ganglia Some of these cells were lymphocytes, but others were atypical and possibly carcinoma cells

## Discussion

The histological features in this case accord very closely with the descriptions of Denny-Brown (1948), Heathfield and Williams (1954), and Henson et al (1954), and the clinical features of all recorded cases have been almost identical It appears that there is a dominantly or wholly sensory neuropathy of distinctive character, resulting from changes in the posterior-root ganglia, posterior roots, and posterior columns, which occurs in association with carcinoma The carcinoma has always been bronchiogenic except in the case described by Dodgson and Hoffman (1953), in which the primary neoplasm was a squamous carcinoma of œsophagus In this case the only available fragment of posterior root ganglion did not show typical "residual nodules" Pathological evidence of sensory neuropathy secondary to degeneration of posterior root ganglia and unassociated with carcinoma has not so far been recorded, although McAlpine and Page (1951) suggested that this can occur

The association between the carcinoma and the neuropathy has given rise to much speculation Denny-Brown (1948) [illegible] attention to the similarity of the histological changes in deficiency of pantot vitamin E in animals, and sug bronchial carcinoma may possibly by-product interfering with the pantothenic acid So far no im been claimed from vitamin therapy suggested that the neoplasm and the may have a common cause, but kno gens are generally so different poisons and act at such different rat nature of such a common cause is conceive (*Lancet* 1954)

Since this form of sensory neurop commonly associated with malignant possibility that it *may* be due to deposits of unusual type has to be Extrathoracic metastases visible on examination are not usually absence of extrathoracic spread was in our case, especially as the growth trated the myocardium and by re endocardial surface of the left auricle access to the general circulation In some factor may prevent the deve typical metastases, and therein may l to the problem Three cases of "c metastatic carcinoma" secondary to genic carcinoma have been recorded ( Alpers 1951) in which macroscopically no were found in the central nervous sy microscopy showed clusters of carcinoma ce perivascular spaces and lying free in the sub the cerebral hemispheres, brain stem, cerebel spinal cord

Because in our case the cells of the "residual found in the posterior-root ganglia and the ce primary carcinoma were morphologically possibility that the nodules contained carcin has been considered (figs 1 and 4) Since, there is no consistently reliable histological m demonstrating isolated clumps of carcinoma possibility that the "residual nodules" in th root ganglia contained carcinoma cells is still Even if carcinoma cells were present it is explain how they could spread from the lun posterior root ganglia and become arranged as at the site of the nerve-cells Provided that could reach the subarachnoid space it would p possible for them to penetrate into the post ganglia in the way described for particulate m Brierley (1950), who showed that an india ink injected into the cisterna magna of rabbits foun into the posterior root ganglia where it had neuronal distribution, outlining the nerve-cells also been shown that india ink injected into th subarachnoid space of the rabbit will find its w lymph-nodes on the posterior thoracic and a walls (Field and Brierley 1948, Woollam an 1953) These experiments suggest a possible ro which carcinoma cells may spread from the l lymph nodes to the posterior root ganglia

Whatever may be the basic cause of the ne lesions, it seems that the demyelination of columns, dorsal roots, and peripheral nerve re secondary degeneration of the central and p processes of atrophic posterior root gangl Denny-Brown (1948) concluded that the muscle in his cases were due to primary muscle de ("polymyositis"), but in our case the atroph showed no specific histological changes Mea practical point is that a carcinoma has been pre pathologically substantiated cases of this dist of sensory neuropathy, and at the time the ne develops the growth may be occult

## Summary

| 60 | 20 | 6 |
| 90 | 8 | 0 |

Each figure represents the mean of two experimental values

their maximum effect at the earliest time interval —15 minutes—and that after 90 minutes the effect had disappeared It has also been found (figures to be published later) that higher concentrations of both compounds may be ineffective or may even inhibit respiration in kidney slices. Both compounds are active at dilutions lower than those quoted, and concentrations of triiodothyroacetic acid as low as $1 \times 10^{-7}$ produce a noticeable effect At all effective concentrations both compounds exert their action without any latent period of action

### DISCUSSION

It appears that the acetic acid analogues of thyroxine and triiodothyronine are effective in raising the oxygen consumption of rat kidney slices in vitro without any latent period of action Neither of the circulating thyroid hormones—thyroxine and triiodothyronine—has any effect on this system without a pre incubation period This leads us to suggest that these acetic acid derivatives may indeed be the forms in which the thyroid hormones act in the tissues

In preliminary experiments, one of us (O T ) has found that a single dose of tetraiodothyroacetic acid 2 mg per kg body weight raises the basal metabolic rate (B.M.R ) of thyroidectomised rats (3 animals) within 0–2 hours, and that the effect wears off after 4 hours. In the whole animal therefore this thyroid like action is very much more rapid than that of thyroxine or triiodothyronine A higher dose (4 mg per kg body weight) did not raise the B M R of thyroidectomised rats this lack of action is comparable with the lack of effect of higher doses of the acetic acid analogues in vitro It would appear from these and from other reported findings that there is a threshold dose for thyroidal stimulation of respiration above which only toxic or inhibitory effects are obtained.

The immediate effects of these acetic acid derivatives on respiration in vitro are worth considering in relation to another system, studied by Thibault and her colleagues.[4,5] These workers have found that thyroxine and triiodothyronine can enhance the sensitisation of isolated intestinal muscle to adrenaline only after a short incubation period but that thyroxamine and triiodothyronamine exert this effect without any latent period of action It is not yet known whether the acetic acids or the amines derived from the circulating thyroid hormones occur in the tissues Experiments are now in progress to elucidate these questions

### SUMMARY

The acetic acid analogues of thyroxine and triiodothyronine have been shown to raise the oxygen con

## METABOLIC ABNORMALITIES IN HYPOPHOSPHATASIA

IN 1948 Rathbun[1] reported from this hospital a metabolic disorder which he designated "hypophosphatasia" His report concerned an infant in whom there was defective calcification of bone matrix, associated with levels of serum alkaline phosphatase considerably below the normal range Since his original description three additional articles[2–4] and two new names ("rickets with deficiency of alkaline phosphatase activity," and "osteodysmetamorphosis fœtalis") have been added to the literature These contributions have helped to establish the clinical features of the condition

We are currently studying a female infant who developed a bulging anterior fontanelle at 3 months of age and who manifests the typical abnormalities in the skull, long bones, and serum

The fundamental disturbance in hypophosphatasia remains a matter of conjecture We record here two hitherto unreported observations which may prove helpful in elucidating the pathogenesis of the syndrome

It has been shown previously that serum from a patient with this condition does not inhibit the alkaline-phosphatase activity of normal serum We have confirmed this and have shown in addition that serum from our patient will produce in-vitro calcification in the cartilage of rachitic rats We present this as further evidence that defective calcification in hypophosphatasia results from a primary disturbance in the metabolism of bone matrix

The association in our patient of metabolic bone disease and mild renal insufficiency prompted us to study the urinary amino-acid pattern by paper partition chromatography as described by C E Dent In addition to the usual amino acids we have repeatedly found a ninhydrin positive substance similar in every property so far tested to aminoethyl phosphoric ester ($NH_2$-$CH_2$-$CH_2$-O-PO(OH)2) The material is also present in the plasma of our patient, and thus is unlikely to be a product of abnormal renal metabolism We have learned from McCance and from Dent[5] that they too have found this material in the urine of an infant with hypophosphatasia Their finding was made independently of ours and at about the same time

The substance cannot be detected in the plasma of normal persons or in urine Therefore we are now attempting to establish its identity If it proves to be aminoethyl phosphoric ester, one might speculate on the possible relation of alkaline phosphatase and the above mentioned phosphate ester in bone formation

On the basis of studies of the activity of serum alkaline phosphatase in parents and siblings, other workers have suggested that hypophosphatasia is genetically determined We have found low concentrations of the same abnormal ninhydrin-positive substance in the urine This finding further supports the sugge hereditary factors operate in the ætiology of phatasia

## SANDAL OF VARIABLE HEIGHT FOR A LIMB-LENGTH DISCREPANCIES

LIMB-LENGTH discrepancies are measurable in practice with a tape-measure and, if the p by putting the foot of the shorter leg on to wood of varying heights This latter method is the one when ordering raises to the shoe or when surgical boots which contain an inbuilt raise.

The main drawbacks of this technique are patient's inability to walk with the suggested position and the considerable discomfort of their body-weight on blocks when the raises are different for forefoot and hindfoot. Because disadvantages the patient's opinion about the height is often inaccurate, and perhaps an surgical shoe made to a prescription obtain testing with blocks has to be altered later, when in the flexible shoe enables the patient's opin more accurate

To overcome these difficulties a wearable pliab has been devised which incorporates a raise of variable from $^3/_4$ in to 2 in and of the sole fr to 1 in

The basic sandal can be made for adults and For adults a length of 10 in can be used for e

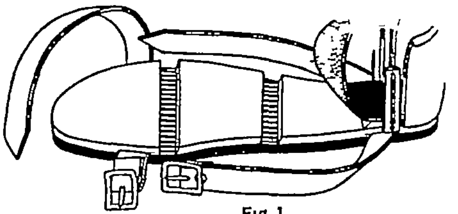

Fig 1

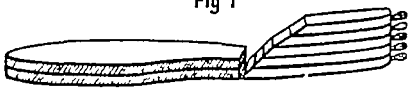

Fig 2

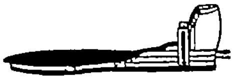

Fig 3

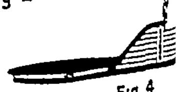

Fig 4

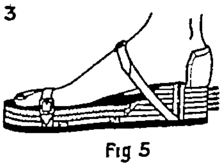

Fig 5

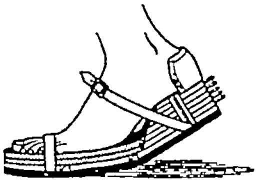

Fig 6

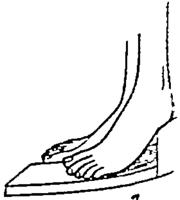

Fig 7

here is no toe-cap, a foot longer or shorter than
dal can be accommodated The design is shown
, where the sole is seen to be composed of three
of five-ply wood $^1/_4$ in thick which are connected
ece of rubber nailed under them which is $^1/_4$ in
nd shaped to serve for either foot Rubber used
-tiling is satisfactory Leather straps pass between
piece and the rubber and between the heel piece
rubber ; these should be recessed into the wood
a flat tread

he heel two aluminium slotted bars are screwed
eel piece to stand vertically at its inner and outer
they are connected by a cross piece of aluminium
like the leather straps, passes across the sandal
the five ply and the rubber Fitting in the
of the slot and able to move up to any desired
is a small heel piece of three-ply on to the top of
s stuck a thin leather insole The combined thick
these is $^1/_4$ in ; the insole is flimsy its thickness
gible, and it presents a smooth surface to the sole
oot no matter what raise is used. To the circum
of this piece of three-ply is attached a sturdy
taken from an old shoe Just in front of the edges
eel-cap small screws are inserted into the three-ply
le it to travel freely up and down in the slots of
l piece. This is the basic sandal.

varying the heel height five separate platforms of
of gradually decreasing length but of the same
and height as the five-ply of the heel piece are
g 2) Each of these has a small hook at the back for easy withdrawal or insertion These are not in any way connected to the sandal proper They lie in the desired position between the aluminium uprights and can be slid in and out easily from the back of the sandal (figs 3 and 4)

For raising the sole five-ply is not used, because this would be rigid Instead floor rubber $^1/_4$ in thick is used Fig 5 shows two pieces laid between the flimsy insole and the segmented sole ; the strap at the front plus body weight keeps them in position The fixed sandal, complete with $1^1/_4$ in heel and $^1/_2$ in sole raise, is shown both during resting (fig 5) and during walking (fig 6) Compare the awkwardness shown in equalising a discrepancy with blocks (fig 7)

The height of the sandal without additional blocks—i.e. as shown in fig 1—is heel $^3/_4$ in., sole $^1/_2$ in By measuring the height of the heel and sole of the shoe the patient is wearing on the normal leg the necessary raise can be assessed accurately

Without taking the sandal off one can quickly alter the raise on the heel by sliding in or withdrawing a further block , and, since each is exactly $^1/_4$ in. in height, a high degree of accuracy can be achieved and with it a high degree of comfort and economy

My thanks are due to Mr W Sayle-Creer for valuable help with the text and to Miss Joan Taylor, of the department of medical illustration Manchester Royal Infirmary for the drawings.

merly lecturer on forensic psychiatry Institute of
chiatry Maudsley Hospital London London :
tterworth 1954 Pp 181 30s

DES papers by the late Sir Norwood East, who
pioneer in seeking to introduce psychological
s into the public treatment of crime, this book
s contributions by three psychiatrists, a probation
and a Metropolitan police magistrate. As might
ected, quality and scope are diverse and it is
determine precisely at whom the book is directed
t is the educated layman The opening chapter
Norwood, on legal and medical advances in
logy is an interesting historical survey of the
of the subject Dr John Mackwood has had
icult task of discussing remedial and educational
therapy during penal detention and he makes a
and not unsuccessful attempt to explain what
-analysis can do, even in the least promising of
ironmental circumstances. Dr Desmond Curran s
iatric approach to the offender is restricted in
says almost nothing of concepts of dynamic
logy He writes :

> sensible view must be that many individuals present
> ather than medical problems as in the case of the
> y On the information available to me this also
> or the vast majority of criminals and this remark
> d by Mr Frank Powell who writes in the concluding
> : About 80% of arrested offenders present social
> han purely medical problems

t nowadays possible to draw so sharp a distinction
n the social and the purely medical aspects
an behaviour ? If psychiatrists are to make any
contribution in this field surely work-shyness and
l behaviour of mainly social origin must be
ly studied In discussing why psychiatric evidence
ot carry more weight in courts of law Dr Curran
eter Scott and Mr Powell put all the blame on
(bad) psychiatrists who make fantastic claims.
might surely have mentioned that lawyers are as
as other mortals to unconscious resistances
Scott in dealing with the phenomena of criminal
our and the efficacy of punishment writes

> ry animal trainer uses punishment even if he is only
> strating his disapproval but he knows full well that
> get nowhere with a frightened or angry animal ; he
> must restore a friendly relationship after the punishment
> punishment of a child is never complete until he once more
> feels approved of Yet [in relation to crime] punishment
> is expected to act unaided.

One might go further and say that punishment will never succeed unless it is applied in the context of an enduring relation between the punisher (or what he represents) and the punished It is the establishment and maintenance of this relation that constitutes the most difficult aspect of the problem of recidivism Mr W Clifford writing on the rôle of probation in the treatment of offenders has concentrated much useful factual information, and has commendably eschewed controversial opinion Mr Frank Powell on the magistrate and the psychiatrist, is stimulating but incautious. His picture of the struggle between good and evil in the heart of every man calls to mind the old Negro spiritual

> In my heart there s a good man living and a bad man too
> They both try to tell me what to do

So far, so good but the song continues :

> Bad man says " You must do what isn't right ",
> And the good-a man the bad-a man they struggle in my heart
> and keep me awake all night

This, surely, is where psychiatry should come in—before the bad a man has won and there is nothing left to do but discuss whether he owes his victory to social or purely medical causes.

## Mechanism of Labour

ERIK RYDBERG M.D., professor of obstetrics and gynæcology University of Copenhagen. Springfield Ill Charles C Thomas. Oxford : Blackwell Scientific Publications 1954. Pp 180 34s

SINCE 1935 students of obstetrics have been familiar with Professor Rydberg s ideas on the mechanism of labour and with his elegant and simple models which illustrate the passage of the fœtus through the curved birth canal Here he discusses in much greater detail his hypothesis that the movements of the fœtal head during labour are determined essentially by the shape of the head and the shape elasticity and plasticity of the soft birth canal '

His argument is supported by well reproduced radiographs and by a series of experiments on necropsy specimens and on carefully prepared models Professor Rydberg discusses not only his own conclusions but also the ideas of others who offer advanced mechanical explanations of the distribution of force on the fœtal head and the derivation of the mechanical couples which produce rotation or flexion. A final chapter present subject in mathematical form, and analyses the ways in an object as asymmetrical as a skull can translate and rotate within the narrow confines of the birth canal Being mainly an account of what happens during normal vertex presentations, the book throws little light on what can be done when all is not normal Professor Rydberg implies that the shape of pelvis and head, at the outset, determines the shape of things to come, and that subsequent moulding and development of the caput make any attempt to modify the pathway difficult and often undesirable

The argument is well supported by evidence, but the author has not measured his torques and forces with internal gauges We may yet come to a fuller understanding of this subject

### Renal Function

*Transactions of the Fifth Conference, October, 1953, Princeton, N J* Editor STANLEY E BRADLEY, M D, associate professor of medicine, Columbia University, New York New York Josiah Macy, jun, Foundation 1954 Pp 218 $3 75

IN this conference nineteen American and one British expert participated Papers were given by Luetscher, Miller, and Bull, and were followed by vigorous discussion The value of these books is somewhat diminished by the long interval elapsing before publication, and the material of the first chapter has already appeared elsewhere

Speakers on the nephrotic syndrome dealt with the presence of aldosterone in nephrotic urine and with treatment by corticotrophin and cortisone Experience was reported of homologous kidney transplants in man survival of these transplants was considerably longer than in the dog, even though prolonged complete ischæmia of the transplanted organ was often unavoidable Results, however, gave little hope of permanent survival of the transplant, except possibly from an identical twin Present views of the cause and treatment of acute renal failure were discussed, and speakers described modern modifications of treatment, such as the reduction of fluid intake to as little as 800 ml each day, reliance on carbohydrate alone if oral feeding is used, and the increasing popularity of intravenous feeding by infusion of hypertonic glucose solutions into the superior or inferior vena cava

The book will be of interest to clinicians concerned with the applied physiology of renal disease, and it draws attention to the present intense research activity in this field

### Techniques de réanimation médicale et de contrôle de l'équilibre humoral en médecine d'urgence

J HAMBURGER, G RICHET, and J CROSNIER Paris Flammarion 1954 Pp 368 Fr 2600

THIS is an unusual book, and correspondingly difficult to judge The underlying thesis is that many quite different diseases are associated with failure of one or more of the regulating mechanisms by which the healthy body maintains its normality, and that we now know enough of homœostasis to enable us to maintain artificially some of these mechanisms until the natural process has been restored

The type of mechanism which the authors have in mind is shown by the subjects of successive chapters the control of respiration, water balance, electrolyte balance, excretion, the blood, and the circulation There is also a chapter on the nutrition of the acutely ill patient, and an appendix containing detailed technical methods The authors believe this to be the first book of its kind, and contend that some things can be excused in a pioneer venture which might be culpable in a textbook of the usual type On reading through some of their statements they were displeased, they say, to find that they had distorted their views by over simplifying them Medical authors, if not readers, will sympathise with them in this experience

Their underlying idea may well be sound and their claim that the techniques described are often life saving is borne out by experience The presentation is much systematised, perhaps beyond Nature, but the principles expressed seem well established There is a fair amount of padding, especially in the illustrations (e g, a drawing of how to make a blood film and a drawing of Tallquist's papers in black and white) On t[illegible] hand, hardly anything has been omitted—though there is no reference to the B L B mask in on oxygen administration which devotes a page (w illustrations) to the nasal catheter Much exper thought are reflected in this compilation and there is architect's design for a future "centre of resuscita

Perhaps the chief value of the book is that it together useful information which must sought in a whole series of special monographs

### Surgical Technigrams

F M AL AKL, M D, associate attending surgeon County Hospital, New York New York and l McGraw Hill 1954 Pp 346 96s

THIS book is made up of a series of line drawings accompanied by a short explanation, of the stages of 36 operations commonly undertaken general surgeon To describe them, the auth coined the word technigrams

Each stage of each operation is clearly shown, there are many drawings for each procedure no less illustrate radical cure of an indirect inguinal hernia end of each operation there is a short account of the anatomy—which the author calls anatomechanics part of the body in question, but it is not clear differs from ordinary surgical anatomy, or indeed technigrams differ from diagrams of operations cedures recommended and illustrated are all standard and acceptable

The book should be useful to house surgeons, and those practitioners who do not operate

---

**British Surgical Practice Surgical Progress** (London Butterworth 1954 Pp 348 42s)—Surgical Practice keeps itself up to date by the yearly tion of a progress volume The 1954 volume is in —original articles, critical surveys, abstracts, and "n The first section is intended to remedy omissions in the work, and the ten chapters include articles on injur bile ducts by Mr Rodney Maingot on injuries of the and bladder by Mr D S Poole Wilson, and on p cerectomy by Sir Stanford Cade An excellent ch the applications of electronics to clinical practice G A Hay, shows the range of knowledge which is n needed by the surgeon The critical surveys co subjects—antibiotics, blood transfusion, carcinoma œsophagus, carcinoma of the stomach, and surgery The abstracts are of a hundred surgical papers, selected as the most important of the year's contrib surgical knowledge The noter up (a functional rath a euphonious term) shows at a glance what additi have been to chapters in the original work, and the present and previous progress volumes the may be found The chaff has been winnowed from by the editors—Sir Ernest Rock Carling and Sir Paterson Ross—and this book continues to be the g of all surgeons striving to keep abreast of their read

**Infant Feeding and Feeding Difficulties** (London J & A Churchill 1954 Pp 277 12s 6d greeted the first appearance of this book by Dr Evans and Dr Ronald Mac Keith as a very compilation for purposes of *reference* In its second it retains this character, and is even more though the authors are careful to make it clear wheth are writing with good personal knowledge of the *described or are mainly reporting* the findings of oth order not to be dogmatic they have treated at equal several methods which are dietetically equivalent, not pronounced in favour of one of them, even grounds *other than strictly* dietetic) it would hav possible to distinguish among them This comprehe and academic impartiality will appeal to the studen junior specialist Two changes of emphasis since th edition are notable On the difficult question of breas before adoption the authors, while still sitting on the now face the other way—towards the bottle Second whole exposition of artificial feeding is now based o milk instead of on liquid milk As before, almo statement of an average is accompanied by a reminde natural variability of infants, who in this book are defended against the rule of the thumb

# Acute Respiratory Infections

hysician who has difficulty in finding his way the maze of undifferentiated acute upper ry infections will be glad to learn that more m the laboratory is on the way First news ame from two groups of workers in the U S A r a year ago ROWE et al [1] at Bethesda l that they had isolated viruses from a large of surgically removed adenoids but the of these viruses to disease in man was then n. Shortly afterwards HILLEMAN and WERNER[2] d the isolation of similar agents from Army with acute respiratory disease or A R D [3] nown as 'febrile catarrh' [4]) In the past Bethesda workers have ploughed a large area portant new field and they have unearthed teresting findings [5]

NER et al [5] tried first to define this group of and then to discover its relation to disease in Nearly two hundred strains have now been from adenoids and tonsils removed at opera- from patients with acute respiratory infections ecause of common properties these viruses belong to a single group They are all epi opic causing very characteristic changes in owing in tissue-culture they are not patho- or ordinary laboratory animals they are nt to other and antibiotics and finally they common 'soluble' antigen which is detected plement-fixation tests Within the group six t serotypes are distinguishable by virus- isation tests in tissue culture and such dif tion has epidemiological significance Forty ains of types 1 2 5 and 6 have been recovered th two exceptions all came from cultures of ls or tonsils removed at operation. The two ons were a type 1 strain which was recovered he pharyngeal secretions of a child with ive pharyngitis and a type 5 strain which rom a laboratory technician who while work h this agent developed sore throat and ear ithout pyrexia Types 3 and 4 on the other vere recovered almost exclusively from persons pper respiratory infections Type 3 virus was in a 2-year old girl with acute febrile rhinitis, gitis and conjunctivitis who was admitted to where apparently she initiated a small ak [6] Within two weeks of her admission there ven further cases five very similar to the first two with mild rhinopharyngitis, and from all of atients evidence of infection with type-3 virus was obtained The clinical manifestations comprised fever for five or six days in six patients pharyngitis in seven with exudate in two, rhinitis in seven cervical lymphadenopathy in five, and conjunctivitis in four This seems therefore to be a distinct clinical entity HUEBNER et al [5] also mention outbreaks of acute catarrhal pharyngitis and conjunctivitis among students in a summer school and their household contacts type-3 virus was found in the throat or conjunctival secretions and oral secretions of seventy-six of these patients It seems too that an agent isolated by NEVA and ENDERS [7] from a child with an illness resembling roseola infantum was a type-3 virus

Type-4 virus was first isolated by HILLEMAN and WERNER [2] from three cases diagnosed as primary atypical pneumonia and two diagnosed as acute respiratory disease during an outbreak among recruits at Fort Lennox Wood, Missouri The association of type 4 viruses with acute respiratory disease has now been further confirmed HUEBNER et al [5] recovered type-4 virus from the nasopharyngeal secretions of six military recruits with febrile respiratory illnesses resembling acute respiratory disease, and DINGLE et al [8] have studied the relation of type-4 virus to certain types of acute respiratory infections by retrospective serological methods using sera collected by the U S Army Commission on Acute Respiratory Diseases during experiments on volunteers and sera from patients clinically diagnosed as having various infections of the upper respiratory tract They found a distinct rise in antibody to type-4 virus during convalescence from acute respiratory disease and from bronchitis resembling atypical pneumonia but not from mild or severe common cold or definite syndromes of primary atypical pneumonia. Of eighteen volunteers who some years ago were inoculated [illegible] is experimentally with acute respiratory disease [illegible] lor have now been shown in retrospect to have [illegible] tive detectable antibody to type-4 virus in their pre[illegible] rva- tion sera, but antibody developed in [illegible] and contrast, of the six volunteers who [illegible] rest symptoms after inoculation five ha[illegible] Only of antibody in their pre-inoculation [illegible] on the the agent used in these stud[illegible] physical as a type-4 virus Studies [illegible] shown respiratory disease [illegible] in three [illegible] disease that in two but not in th[illegible] been an agent similar [illegible]

Outbreaks of in[illegible] physique provide the most f[illegible] work of the causal organ[illegible] on the such outbreaks [illegible] r It is logical importance [illegible] lated to communit[illegible] omorphy simple ass[illegible] Channel does not [illegible] owment In or[illegible] at the ultra[illegible] bo publish[illegible] vision of Hum[illegible] serological survey [illegible] in volunteers with [illegible] sera from a group [illegible] in three hospital [illegible] serotypes by a virus [illegible] tissue-culture Antibodies [illegible]

were quite prevalent in the young age-groups, over 30% of infants aged 6–11 months already had antibodies to these two types The findings in older children accorded with the observation that most of the viruses recovered from surgically removed tonsils and adenoids of children attending the same clinics were of types 1 or 2 Antibodies to the other four types were not so common, but there was a sharp rise in the frequency of antibodies to type 4 from 25% in those aged 6–15 to 71% in those aged 16–34 This suggests that type-4 virus may have been more prevalent in that area fifteen years ago, but perhaps such a conclusion is best deferred The volunteer studies have not yielded much further information Infected nasopharyngeal secretions and tissue culture fluids containing active virus were administered intranasally to adult volunteers Few objective signs of illness resulted, although most of the volunteers showed serological evidence of active infection No differences were noted between volunteers who had pre existing serum antibodies and those who had not

The discoveries of the past year add greatly to our knowledge of this difficult subject, but they also leave many questions unanswered In particular, there is great need for more facts about the rôle of these viruses in the host of minor respiratory illnesses encountered in general medical practice The laboratory will soon be able to help physicians by adding the complement-fixation test with these agents to the techniques for investigating respiratory virus infections If the suggestion of HUEBNER et al is accepted, this group of viruses will henceforth be known by the name "adenoidal-pharyngeal-conjunctival" agents Perhaps the best justification of this title is that it will soon be mercifully abbreviated to A P C—initials which hint at a suitable treatment

## Indices of Heat Stress

IT is not easy to assess the physiological effects of work in hot conditions The main environmental factors are the temperature, humidity, and rate of movement of the air, the amount of radiant heat, and the clothing, but equally important are the physiological factors—metabolic rate, acclimatisation, and availability of water and salt to replace losses in the sweat Of the various methods of measuring heat stress, the only one that was at all widely used until the 1939–45 war was the two effective temperature (E T) scales These scales, evolved by YAGLOGLOU et al[1–3] in 1923, have proved of considerable value, although designed as an index of comfort, they were found also to predict the physiological state They take into account the dry and wet bulb temperatures and the rate of air movement, but they made no allowance for radiant heat until BEDFORD[4] suggested that the globe-thermometer temperature should be used where this differed from the dry-bulb temperature

In the late war the E T scales were used at first for defining tolerable conditions in ships operating "closed down" in the tropics But the validity of the scales in severe conditions had not been fully tested, and the effects of clothing and acclimati imperfectly understood Research on th was therefore undertaken in speciall climatic chambers at the National Hosp Square, where it was found that, although the E T scales measured the stress accurat certain circumstances they could be mis for instance, by underestimating the d effects of still air on men working in h environments[5,6] Since it did not seem p modify the E T scale to correct these errors, and his colleagues[7] at Queen Square constructed an alternative nomogram, based o obtained on acclimatised volunteer naval This nomogram was designed to predict th logical state at the end of four hours in t conditions, the unit of measurement being hour sweat loss The predicted four hour s (P$_4$SR) derived from the nomogram was f correlate very well not only with the observ for sweat loss but also with the final rectal tures Since the pulse rate varies in parallel rectal temperature the P$_4$SR does in fact giv estimate of the physiological state as well a probable salt and water requirements

Mr F E SMITH[8] has now compared the of the P$_4$SR scale with that of the E T scale, to detailed statistical analysis some of th of the Queen Square workers He divided into four main groups according to the work clothing, and compared the two indices ability to predict the sweat losses and the temperatures On all counts the P$_4$SR scale superior or equal to the E T scale The P$_4$S more practical since it allows for the amount and the character of the clothing and guide to the amount of unevaporated sw is important in determining the degree of The E T scales measure the predicted phy effect in terms of that temperature of still air, s with moisture, which would have the sa as that of the environment under considerat relate an effective temperature to phy response it is necessary to consult graphs particular combination of work and clothi curves bear a logarithmic relation to the and rectal temperature and are very di remember This is one of the major defects E T scales On the other hand these scales to understand than the P$_4$SR scale, and th tion is quicker Moreover the E T scales wide range of environments from very cold hot, whereas the P$_4$SR scale is concerned only regions in which sweating may occur The tages of the E T scales seem to have SMITH considerably, and he has devised simple and ingenious additions to the E T no by which the amount of work is taken dir

though again the result is given in terms of ure These additions are founded on the f the Queen Square workers, but only at of metabolism, and thus the new nomogram l largely from intrapolated and extrapolated In doing this SMITH has made the question mption that in all environments increase ears a linear relation to the resultant increase logical effect Until an accurate and fully nsive scale can be constructed embracing nments and including extremes of heat and ould perhaps be wiser to use the P4SR scale if conditions are not severe the E.T. scales ove reasonably satisfactory

## Body-build and Temperament

ea that a man's body build is related both mperament and to his proneness to disease om now The difficulty in testing this idea to devise good objective methods of recording The Hippocratic division into *Homo* s and *Homo apoplecticus* was a useful first ation. Others since then have been content ognising continuous variation, to make the vision between those who are relatively their height (leptosomes, asthenics) and those heavy (pachysomes, pyknics) REES and ,[1] for example following BURT in the use analysis, found in a sample of soldiers one actor for general body size and another ype factor contrasting length with width umferential measurements But as is well o boxers and wrestlers the same height atio, even in well trained men with little include physiques which differ widely in strength and skeletal form and a satis classification must include some estimate variation HAMMOND[2] has applied factor to measurements of British and American . He too found a general size factor and a tor distinguishing those excelling in length se excelling in circumferential measurements ddition in boys he found a second type factor istinguished those who were rotund and not y broad (excelling in circumferential measure fleshy parts, but with relatively small bones) ose who had a broad trunk and big bones. more intuitive approach SHELDON[3 4] dis- es between three components of physique have much in common with HAMMOND's , except that SHELDON is not concerned with size His components are (1) endomorphy rised by ready accumulation of fat deep ound skull and thick upper arm and thigh atively thin wrists and ankles (2) meso- characterised by big muscles and bones ut not thick chest cubical skull, and large s and calves in relation to upper arms and and (3) ectomorphy characterised by linear arrow chest narrow face long thin limbs, t bones SHELDON types a person by giving core for each of the three components. This is objective in that independent observers will arrive on about the same grading from measurements on a correctly taken photograph The somatotype has been shown to remain more or less constant in adult life, though it is not yet certain whether it can be estimated accurately in childhood

Full understanding of the constant elements in body build will come only when the genetic factors have been determined but this is no reason for not trying to associate temperament and disease-proneness with linearity of build or with SHELDON's somatotypes The first more or less scientific attempts were those of KRETSCHMER who distinguished between pyknic athletic, asthenic, and dysplastic types He found that the pyknic were especially liable to have a cyclothymic personality and to develop manic depressive psychosis, whereas asthenics were especially prone to schizophrenia While some psychiatrists have confirmed his findings others have not—partly, no doubt, because his assessment of physique was too subjective REES[5] related the score in his second factor—that of linear or stocky build—to neuroticism in soldiers and found that hysterics tended to be stocky, and obsessionals and those with anxiety states to be linear SHELDON[6] has related his three components of physique to three components of temperament—viscerotonia somatotonia cerebrotonia—which are associated with endomorphy, mesomorphy, and ectomorphy respectively Viscerotonia is characterised by qualities which include complacency, love of comfort enjoyment of food, need of affection, and sociability somatotonia is characterised by assertiveness pleasure in bodily action and insensitivity to pain cerebrotonia is characterised by restraint self consciousness sensitivity and love of solitude Gradings for these qualities of temperament are not as objective as the gradings for physique but common observation suggests that the associations are real ones, and as objective tests become available it will be interesting to see how they correlate with physique Only preliminary reports have so far appeared on the association of somatotype with mental and physical disease For example GERTLER et al.[7] have shown that those who develop early coronary artery disease are usually endomorphic mesomorphs

An interesting sidelight on associations of physique with temperament has come from the work of TANNER[8] and PARNELL[9] in this country on the relation of somatotype to choice of career It is natural that choice of sport should be related to physique no one who is not high in mesomorphy could hope to excel at rugby football while Channel swimmers usually have a considerable endowment in endomorphy as well as in mesomorphy But the association of somatotype with occupation is presumably mostly through temperament In the U.S.A. GARN and GERTLER[10] showed that workers on the floor of the factory tended to be lower in ectomorphy and higher in the other two gradings than those in the research departments This was not a social class or educational difference since the men on the managerial side of the factory differed even more

from the research group in their relative lack of ectomorphy In this country TANNER[8] has shown that officer-cadets at Sandhurst are on the average more mesomorphic and endomorphic than undergraduates at Oxford, while preclinical students at a London hospital were intermediate between the Sandhurst and Oxford groups PARNELL[9] has found that at Oxford medical students are more mesomorphic than the remainder, and that at Birmingham dental and engineering students are more mesomorphic than students of physics and chemistry Moreover, the whole distribution of somatotypes at Oxford is more central than at American universities studied by SHELDON The extreme mesomorphs and the extreme ectomorphic endomorphs were absent from the Oxford group, and there is a relative shortage among them of extreme ectomorphs These studies relate somatotypes to choice of, and selection for, career, but association with success in career is of greater practical importance As a first step PARNELL[11] has attempted to relate the somatotypes of Oxford students to the type of degree they achieve in the final honours examinations His numbers are small but suggest real differences Notably there is a tendency for those predominating in mesomorphy

to get their fair share of first-class
relatively few thirds, the great majorit
seconds Understandably this group were
to have made the biggest contribution to
sport The highest proportion of firsts
near-central endomorphic ectomorphs The
ing findings need confirmation and further
one possible source of confusion is that fir
awarded more generously in some subj
others There is no reason to suggest th
is in any way related to intelligence, and
type is related to academic success
through temperament Perhaps the highly
among extreme ectomorphic
insufficient energy to get to the university
intelligent extreme mesomorphs may pref
their powerful grip on adult life early witho
time on non-vocational education.
moderately high mesomorphs, if they g
university, have sufficient drive at least to
a second, but may be too restless to get a fir

The basis of these probable, though
proven, relationships between physique,
ment, and proneness to disease is uncertain
of the association may be basically genetic
to the multiple effects of single genes

# Annotations

## MALARIA IN THE AMERICAS

THE inception of a five year campaign to eradicate malaria from the entire American continent has been announced by the Pan American Sanitary Bureau, a subsidiary of the World Health Organisation The extent of the undertaking can be judged from the fact that 135 million people in the Americas live in potentially malarious areas—60 million in regions where the disease has been suppressed, 45 million in "protected" zones, and 30 million in unprotected areas The aim is to extend control to all the malarious regions, and to intensify it to the point where transmission ceases If transmission can be prevented for a few years gametocytes of *Plasmodium falciparum* or *P vivax* will not recur and the disease will disappear

Twenty years ago such a scheme would have been fantastic But the residual insecticides have made possible very large and successful antimalarial campaigns—for example, in the Mediterranean, in the U S.A , and in Ceylon The highest levels of control have been achieved in the more temperate climates, where both the plasmodium and the anopheles are seasonally checked by cold Much of the American territory already conquered falls into this category, whereas it is not unlikely that the areas at present "unprotected" from malaria are tropical, undeveloped, and largely inaccessible Furthermore, recent events in Central American States suggest that political unrest may hamper international operations

In most previous campaigns there has been only one main vector to attack But in the vast American territory many different anophelines predominate in different regions (e g , *A freeborni*, *A quadrimaculatus*, *A albimanus*, *A darlingi*, *A* (*K*) *bellator*, and *A pseudopunctipennis*) The problem of suppressing transmission is different with each of these mosquitoes Their very diverse breeding habits are probably unimportant, for it is almost certain that they will be attacked in the adult stage by residual insecticides The most important characters of the insects are (*a*) their "domesticity" (i e , whether they bite man in or near houses and will
rest on treated walls), (*b*) their sensitivity
insecticide, and (*c*) the possibility of their d
insecticide-resistant strains Resistance to
is a serious hazard for which we must remain
Greece, insecticides gave perfectly satisfacto
for several years, but last year malaria was
in 144 villages owing to resistant strains of A

Malaria eradication, though not so difficult
eradication, demands much more effort th
control An attempt at complete suppression
such a vast area as North and South America
for all the optimism and drive traditionally
with the New World

the pelvic brim and on an anteroposterior film mistaken for the lower bowel The distribution the intestine is not the only diagnostic feature resence of an obstruction will lead not only to passage of air but also to gaseous distension of l, and this gives rise to characteristic appear h as the gross distension of the stomach and of the duodenum in duodenal atresia Radio ust always be taken with the infant upright rectal atresia when the patient must be inverted tallic object placed in the perineum so that the een the gas filled lower bowel and the skin may ated Barium by mouth has no place in the tion of the newborn infant and it may be s if there is vomiting But a barium enema is for the diagnosis of low intestinal obstruction Hirschsprung's disease for there is no other of recognising the typical narrow segment [1]

y of the newborn infant has advanced strikingly ast decade, and more accurate diagnosis of l obstruction by radiography has played no t in this progress

## DIETARY SODIUM RESTRICTION

U.S.A the value and dangers of dietary sodium n have been concisely and authoritatively sed in excerpts from a report prepared by a small e for the Food and Nutrition Board of the Research Council and the Council on Foods and n. The first excerpt [2] deals with the physiology n, and the *normal response to sodium restriction* ond [3] shows how the indications for sodium m have been extended since in 1901 Achard and first appreciated the connection between salt d the formation of œdema in cardiac failure In to cardiac failure, the conditions in which sodium n may be of value are now held to include sion renal disease, cirrhosis of the liver toxæmia nancy and Ménière s disease The report is ely enthusiastic about restriction of sodium in edema œdema relating to cirrhosis and toxæmia nancy The verdict on the value of restriction in sion and Ménière s disease is hot proven — carries the stigma which in fact if not in theory h such a verdict The dangers of sodium restric n general treatment for renal disease are empha n relation to the possibility of 'salt losing s," and the appearance of a low salt syndrome, ydration and a precocious increase in the blood el. The report points out once again that in the at of œdema the *restriction of sodium must be* , with a daily intake not exceeding 500 mg quires a considerable effort by the doctor or n in planning the diet and a greater effort by the in consuming it ; *the labours of both (in America)* e lightened by the requirement of the Food and dministration that foods in such a diet shall be with their sodium content per 100 g and per ; and apparently *such foods* may be had in

tunately painstaking adherence to such a diet l to achieve its objective and may even lay the open to hazards [5] including inadequate general n and vitamin deficiencies ; and a greater range sodium foods and the administration of vitamin ents are recommended The sodium depletion ne' may appear especially when a low sodium conjoined with *mercurial diuretics or when* or central heating provoke significant sodium loss in the sweat and the report recommends that the serum sodium level should be checked weekly or even more often Loss of responsiveness to mercurials and dehydration *with a rising blood urea level* may also be due to excessive sodium restriction

On this side of the Atlantic we are generally less rigorous in demanding sodium restriction We try to atone for our shortcomings with mercurial diuretics, or with cation exchange resins to bind *some of the dietary* sodium after it has fulfilled its office of seasoning our food But occasional patients derive psychological strength from a strict regimen and it is perhaps in them that we should look more closely for the harmful side-effects less latent in a low sodium diet.

## ANAEROBIC COCCI

ANAEROBIC cocci are common commensals of man but they are all sensitive to penicillin and *so are not of great* pathological significance today Formerly *the anaerobe Streptococcus putridus* was recognised as an *important* cause of a dangerous kind of puerperal infection This organism and closely related strains still comprise the commonest group found in puerperal pyrexia and they are probably the cause of other forms of suppuration—for example anaerobic streptococcal myositis In the days before penicillin reduced the pathological significance of the anaerobic cocci these organisms were in a sense 'unpopular' with bacteriologists. Partly this was because in many laboratories methods for isolating anaerobes in pure culture were not part of the routine and partly because critical study often disclosed that cultures of cocci thought to be obligate anaerobes were only facultative anaerobes But perhaps the chief reason why the anaerobic cocci were not welcomed as objects for study and identification was that their taxonomy was chaotic : the most widely accepted scheme of classification comprised eight genera with thirty two species and several subspecies Many of the species were so poorly described that their names could not be justified and some of the criteria for differentiation of species were so questionable that the whole picture appeared confused in any light Still worse the biological characters of a single strain were liable to change unpredictably between one laboratory and another and even within a single laboratory between one batch of medium and another

Bacteriologists owe a debt of gratitude to Prof Ronald Hare and his colleagues [1-3] who have done much not only to bring order into the taxonomy of the anaerobic cocci both gram positive and gram negative but also to explain the reasons for some of the variability in the fermentation and other reactions of these organisms It now appears that the exact composition of the medium and choice of test substrate is very important : sulphur compounds are required for gas formation by some strains fatty acids must be present in the medium to allow other strains to show fermentative activity and still other strains can attack organic acids but not carbohydrates With media containing peptone agar or digest broth, enough of some of these substances may be present as impurities in some batches and absent from other batches to account for the hitherto mysterious variability in the reactions of the anaerobic cocci

By methods and in media which they fully describe Hare et al have examined 233 strains of anaerobic cocci Of these 141 were commensals isolated from healthy people—from such situations as the nasopharynx mouth skin intestine, and vagina The remaining 92 strains came from material aspirated at bronchoscopy (10 strains) abscesses in lungs removed at operation (3 strains) sputum from cases of chronic lung infection (10 strains) the genital tract of cases of puerperal pyrexia (60 strains)

and other forms of infection (9 strains) Of the 233 strains all but 27 were classified in one of nine groups based on the fermentation of five carbohydrates and five organic acids From the results of this work it is now evident that each area of the human body tends to possess a rather restricted number of groups of anaerobic cocci The strains of group 1, which correspond to the species named *Streptococcus putridus* (Schottmüller), seem to have more certain claims to pathogenicity than those of groups 2–9 But most of these strains will ferment carbohydrates or organic acids such as pyruvate, as a result they may so increase acidity as to impair the antibacterial efficiency of local defensive mechanisms In this way the anaerobic cocci might promote infection with other organisms present in the same situation, and so might be more important than is generally supposed

## PROTECTION AGAINST IONISING RADIATION

THE injuries from ionising radiation can be classified into two groups—deep and superficial Of the deep injuries damage to reproductive organs and blood-forming tissues are particularly important Experimentally malignant tumours have been produced, and in radium and X-ray workers the incidence of leukæmia is significantly higher than in other medical workers and the general population Superficial injury most commonly involves the hands, and the lesions have included epilation, telangiectasis, necrosis, and carcinoma

In his presidential address to the section of radiology of the Royal Society of Medicine, Dr J F Bromley[1] described some of the ways by which, in the absence of simple precautions, a considerable radiation risk can arise in routine hospital practice He recalled an investigation some years ago in a gynæcological ward, in one corner of which were grouped "for convenience of nursing" seven patients undergoing radium treatment Films hung at intervals along the walls of this ward recorded, over five days, dosages ranging from 0 1 to 3 0 rœntgen units, the total radiation to which the nurses were exposed must therefore have been dangerously high He pointed out that unnecessary exposure of nurses to high doses may take place during "back rounds," or as a result of over-solicitous attention to patients with implanted radium during recovery from an anæsthetic To obviate these and similar risks, he said, all procedures that had to be carried out near these patients should be executed as speedily as possible, and hospital matrons must be fully aware of the importance of keeping the numbers of nurses engaged on "radium duties" up to establishment

Effective screening of those at risk is seldom possible Formerly it was accepted that a worker could safely receive up to 1r per week, but in 1950 the International Commission of Radiological Protection put the "tolerance" dose at 0 3r per week, measured in air, for whole body radiation, and at 1 5r per week for the hands and forearms

To check that the tolerance dose is not being exceeded specially prepared films or small pocket ionisation chambers, measuring dosages as small as 5–10 milliroentgens, can be carried, and it has been usual to do routine three monthly blood-counts Various workers have shown gross correlation between blood changes and definite over exposure[2–5] Mole[6] has now made a critical survey, in an effort to determine the value of blood-counts in defining damage to the blood forming organs before irreparable harm has been done The possible changes in the blood count might fall into three groups

(1) A decrease in the count without contin
where the blood forming tissues are not irrepara

(2) A sudden terminal fall, where repair has k
destruction until the ability to repair is exhausted

(3) A gradual fall, assuming that the abili
diminishes with extension of marrow damage

In practice it appears that the changes o
of one of the first two types, which suggests
blood counts can be of only limited value L
irradiated some guineapigs at eighty times an
twenty times the normal tolerance dose In
group the white blood cell count fell by 50%
latter by only 20%, and in neither group was th
sive decrease in cell counts to indicate irre
damage Yet at the end of two years the
among the guineapigs which had received the
was twice that of controls Apparently ly
at least as common a sign of damage as n
but even with gross damage neither may be
in one case of aplastic anæmia due to radiatio
blood cell count was 4700 per c mm on the d
In any one person the white blood-cell coun
considerably, and it takes time to establish
base line Furthermore Mole questions wheth
in the number of white cells in the periphe
related to the extent of the underlying marro
and he suggests that any changes in the whit
counts of radium and X ray workers are m
be due to factors other than radiation The
cell count, he concludes, cannot be relied on t
warning of serious damage

## SKIN TESTS IN ASTHMA

ASTHMA is notoriously difficult to treat, and
of treatment are hard to assess hence the
of remedies, and of opinions on their val
testing followed by desensitisation may seem
well as simple, but this method rests on two
assumptions (1) that attacks are caused
with allergens, and (2) that skin tests can ind
allergen is responsible While the former
may be correct in certain patients, the lat
unproved

Herxheimer et al[8] have investigated the sk
in 300 patients with allergy affecting the
system, and 100 normal people More tha
patients had asthma, and the remainder
rhinitis or hay fever The "prick" test was
twelve extracts of allergens One or more of th
gave a positive reaction in 95% of the patient
in 50% of the controls In 21 patients the
repeated on different days, and the results were
in only 3, in the rest variations were consid
patients were judged to be definitely sensit
or more specific allergens, but in 6 the sk
react to the incriminated allergen, and in t
remaining 45 at least one skin reaction did
spond with the clinical evidence Herx
conclude that skin-testing cannot be relied o
a causal allergen They suggest that it shoul
in only two circumstances (1) where sym
thought to be due to non allergic causes and a
negative result would give helpful confirmat
(2) where in a suspected allergic disorder th
other evidence of specific allergy In this s
of case positive results may help in selecting
for direct testing of the bronchial or nasal
though, as Herxheimer et al point out, the
mucosa and the skin do not always react to
allergen This work suggests that skin te
scarcely any value in these common respirator

## REDICAMENT OF THE FAMILY IN THE MODERN WORLD *

HENRY V DICKS
M.A M.D Camb F.R.C.P
TO PSYCHIATRIST THE TAVISTOCK CLINIC LONDON

than twenty years ago Ogburn [1] in the U.S.A hat the rapid alteration in social and techno nditions had profoundly affected the economic ad even the personal aspects of family life But he *family is everywhere exposed to change and* chment by other institutions (e g the State) mains the social atom—the irreducible unit of ganisation Why? Because the human infant re than any other living creature is endowed biological need for the intimate experience of rotective mothering Hence the human mother l many animal mothers requires the security of tself satisfied and cared for in order to answer l in the infant For this bio psychological func e conjugal family there is no adequate substitute ties safeguard it by marriage customs The tion and adaptation to changing conditions of this l institution is the prime consideration of all of rned with mental and communal health

### FAMILY TENSIONS AND MENTAL HEALTH

n psychological discovery has demonstrated in ting fashion that for the human child other beings especially the mother, are the most nt factor in the environment and there can no e much doubt that broadly speaking healthy levelopment is founded on an infancy spent in a e, stable, loving family The reverse side of the —psychopathy and neurosis in deprived children— more fully documented, and we are all becoming f the links between unhealthy emotional con n people's childhood and their later psychological onomic nervous disturbances Psychopathology happy parent-child relations are, in a sense ble

intensive personal studies of a large number of marriage failure I can confirm that there is a nt relation between an unhappy family back of the spouses and their incapacity for a good e relationship [2] This is also found in Slater and nd's study of London working class marriages in and *non neurotic samples* [3] The crucial factor o be not a physical break by death &c in their d home but rather the images and memories of *unhappiness* These images and memories may ension in the minds even of people who show te adaptation in all other spheres of life Marriage most special and intimate human *relationship* to light neurotic faults and distortions of per which can remain undiscovered in other less g situations—even in war experience

Psychic processes which interfere with good marital *s appear to me to stem from disappointment in* tion of how the marriage partner should play his exual marital role I find that people who are d to fail in marriage love and marry not a real person but a more or less distorted image of inner fantasies projected into the partner The projected image may represent repressed aspects of the subject's own personality or more frequently the residues of still potent internalised parent figures Unhappiness and recriminative behaviour in open or concealed form break surface because the partner does not answer the secret wish for a parent surrogate Intimate contact reveals the lack of capacity for dealing with the real partner in a mature and tolerantly loving way and demonstrates the immaturity or crippling of the emotions which have developed only to the level of the ambivalent demanding (because deprived) child Once there develops this neurotic attitude towards the marriage tie it tends *to invade other spheres of life of the individual : parenthood* work and capacity for enjoyment Escape patterns and neurotic defences are mobilised in all the familiar forms

Even if they attempt it the disturbed couple can rarely conceal their tension and hostility from each other or from their children Children internalise in love or in fear and anger what they see and feel about their parents just as the parents had internalised the unhappy angry forbidding images of *their* parents In this way the deprived child is likely to become an unsuccessful marriage partner in his turn Thus an increase in the incidence of marital breakdown in a community will directly swell the numbers of conflict torn insecure children who have not learnt to identify with good parents Because they have not done so they will be unable *to give out secure affection in adult life as fully* as they should in their marriages or in the wider sphere of social obligations. I need not labour the danger to society if this were allowed to go on unchecked It would be ironical if we were to see an advance in physical well being (due to our efforts at public education and hygiene) go hand in hand with a disintegration of social and personal relationships—i e, of mental health

My experience based on the observation of guilt feelings in unhappy marriage partners and of their attempts to improve their relationships and to protect their children from the effects of their conflicts leads me to think that deep down most of mankind cherishes the values of marriage and of the happy secure family as perhaps the greatest and most natural source of a sense of satisfaction and personal worth We have to seek the causes of the disturbed or broken marriage in the development of their personalities *under given social* conditions

### THE MODERN FAMILY

A generation ago we might have been moved to say that we needed an army of psycho analysts to help these unhappy people by individual therapy—both of parents and children That they need help and treatment remains just as true today but we have now begun to broaden *our concepts of mental ill health to include not only* personal but also social aetiology I propose to offer some ideas on the possible connection of the disquieting phenomena of increasing marital instability and divorce in Western societies with the rapid changes in our communities We know that there were marital unhappiness parental neglect crime mental disease and brutality in every epoch of history Our concern and our awareness of it in our era are due to the development of the psychological and social sciences which have made us think of these matters as coming within the realm of research treatment and prevention—just as the development of general medicine and hygiene have made us think of epidemics and of surgical catastrophes no longer in terms of inevitable calamities but of controllable events Our thinking may be still tentative because our knowledge is limited It is important that we here affirm

h, H V Experiences with Marital Tensions in the Psychoal Clinic *Brit J med Psychol* 1953 26 181

r E, Woodhead M Patterns of Marriage London 1951 the similarity in principle with general hygiene And we know enough to propose action with modest confidence in some areas

In traditional societies such as are still the rule in many parts of the world, as they once were in Western Europe, the family or kinship group conferred economic autonomy, division of labour, and human security and companionship Its functions were an integrate of economic, cultural, and personal cooperation as an aid to survival This large primary group shared values, and religious and leisure life The rôles, duties, and obligations of each kind of member were clearly defined by custom and taboo Thus such a family was not only a rich and meaningful milieu it was also often the *only* milieu—school, workplace, and transmitter of the cultural heritage from generation to generation Because of the variety of figures who composed the group, it was possible for each member to spread his loves, hates, and many other emotions between parents, grandparents, uncles, aunts, cousins, and siblings, yet within prescribed limits It was a narrow but a safe world—each knew his place and status

The modern urban family with few children, which social mobility has now made typical of our Western society, is a much shrunken successor to this traditional kinship group It has developed rather quickly—over only a hundred years or so—and thus it shows many contradictory or conflicting stresses within it Technology with its demands and opportunities has imposed its values on such a family The children are expected to surpass the parents in education and skills, and often to found their own families far removed in physical and in social space from the parent generation The development of dormitory suburbs around the new industries, &c, into which newcomers settle, or into which families move as part of "slum clearance" schemes, has produced a degree of social isolation or atomisation, where each little family may remain, and often feels like, an island amid a "sea of strangers" Social mobility and rootlessness may drive many young men and women who have grown up in such a milieu to marry each other from no deeper motive than loneliness This is the social aspect of the marriage in search of parent substitutes The monotony of industrial working life and the lack of wider social relations now drive the couple and their too few children to expect most emotional satisfactions from each other—with the consequent exaggeration of emotional demands The marriage is expected by the partners to supply them with all the relational security previously spread over a wider and varied kinship group several generations deep The intensity of feeling is passed on to the over valued children who are having to work out their developmental emotional conflicts within this limited "psychological space" Moreover, urban life, with its real dangers, and its cramped living conditions for the majority, makes a small child's adventures into independence a matter of anxiety, and often a cause both for over-protection[4] and for resentment by the parents, who would like to feel free to indulge their unsatisfied cravings for the "good life" among the attractions of the city

For the fortunate minority, life in big cities does indeed offer opportunities for wide and varied experience and social relations This minority perhaps attains in our civilisation a breadth and a universalism undreamt of in former days This limitlessness of development is in theory open to all, and justifies the loss of the old securities But it can be achieved only if emotional background at family level, coupled with good abilities, has adequately equipped the personality for metropolitan life As yet there is fear of freedom, and
even escape from freedom, because in
personal responsibility Such is the contrad
the present urban family pattern Technolog
demands personnel trained to independen
reliance The family, in its isolation from
outside contacts, still asks from its children
virtues of dependence, it clings to the childr
the parents live vicariously through the ch
neither generation has other kin to fall bac
values which the parents' parents hold ar
those of the children

This process is not perhaps so clearly se
long urbanised communities who have
tions to this way of life—such as in Viennese, P
Londoners It is very marked in new com
such they can be called), where the housewife
is driven into conflict owing to loneliness, with
at the factory all day and in no mood to share
burdens when he comes home She resents
child dominated life, and is unconsciously
towards her social role The children inter
what little pleasure she and the husband may
before their arrival She may take out her
on the children and on the husband, and bot
begin to long for escape No traditional ties
but only inner loyalty and personal respons
there to help stabilise them[5] Moreover, the
has introduced a conflict of sex rôles into the
married women, because it offers equalities of
as workers and competitors with men

It is the experience of medical practitioners
that in secure, old-type rural communities
much less common than in dormitory
F A Bevan[6] has stated that in his practic
quarters rural, a quarter industrial settlement
all the problem children, the marital difficulties
neuroses come from the industrial families

Modern child psychiatry has long recogn
stress in a family cannot be compartmental

There is no doubt in my mind that the rathe
change in kinship structure and emotional "
ness" which the Industrial Revolution and its c
social mobility and urbanisation have brough
accounts for a great deal of the malaise in fam
not to speak of the destructiveness of mod
which themselves reflected the discontents of

---

[4] Overprotection on the part of ambivalently anxious parents is psychologically also a "deprivation"—of the child's normal need to assert its independence

[5] We may compare the change from traditional to moral sanctions to the biological processes of exoskeleton and developing an endoskeleton.

[6] Bevan, F A Contribution to discussion on Family and the General Practitioner British Medical annual meeting Cardiff, 1953 Unpublished

cott Parsons [7] has pointed out the nature of this kinship situation for the American nation

### THE COUNTRIES OF RAPID CHANGE

ve reflect that the stresses and strains centred mily are great and potentially destructive in societies, what can be the prognosis for those "undeveloped" communities which almost have begun to industrialise and to attract ibers away from the land from kinship systems ure patterns much more compelling and less listic? After all Western culture has developed nd—at least since the break up of the feudal has emphasised the conjugal family as the unit structure Under the authority of Christian it has been accustomed to regard the free ip of husband wife, father mother rôles as the *motional security*

will happen in the minds and feelings of scores nds in India, China or Africa now pouring out ir villages into new industrial towns? How make sudden breaks with their different culture of marriage, oriented around different values and systems?

so new centres of industrial change we shall need *plicit agencies of mental hygiene and welfare* urgently as, in the cities now rapidly enlarging e this flow of—yes—displaced persons we shall er public health installations such as drains and ters and inoculation stations

not competent to speak in detail of the effects of gical change on non European societies but ple, it would seem that wherever modern industry in settlement appear there old kinship systems p and the small conjugal family becomes the unit for the security and emotional satisfactions embers, parents and children. We know what it is subject to It therefore becomes the focus r mental hygiene We are likely to see repeated he same phenomena as have accompanied the ation of women through industrial work in and the same relative diminution in assured edominance These will be due to the intensifi f conflicts and doubts in the playing of the sex etween traditional internalised parental standards pressures of present reality The first generation be so badly off but the full impact may well fall children

social and economic policies which ignore or ene the optimal transition from the traditional *ictual kinship situation will increase this conflict* and new values and pressures and lead to wide marital catastrophes broken homes and derelict without stable values and without safe good to identify themselves with

perhaps already too late in many areas to avoid just as in the Soviet Union rapid forced indus ion with its concomitant deliberate loosening of ties led to the tragic phenomenon of the *bezpri* children in the early years of the régime com the authorities to a complete turnabout in defence old fashioned family mores

### ACTION?

e are in my opinion two levels of possible action

TM

is politico-social planning for the creation in the ban communities of effective (if at first artificial) utes for the kinship group—to make the factory o settlement round it a friendly good neighbour in which from the start the working families can feel supported and have a plot of garden to cultivate to prevent rootlessness and *Lumpenproletariat* deterioration[8] with facilities for adult education in skills in the new living including parentcraft All the social sciences—psychiatry psychology, anthropology, sociology and economics—must be brought to bear on solving the problems of each such new centre in terms consonant with the history and traditional culture pattern of the people as a whole But this is not enough The goal cannot be the creation of shepherded supervised, and welfare minded" communities. That is only for the period of acute dislocation and readaptation We surely want communities so structured as to be secure and mature enough to progress towards self management and democratic responsibility

Furthermore—and this applies to Western as well as to new communities—we need to work out a consistent policy based on mental health values, in regard to families. Our clinical insight tells us that young children must have safe and continual mothering But our fiscal and economic trends as well as the emancipatory revolt of urbanised women pull the young mother away from her maternal rôle The State tends to supplant the parents as the providers of goods and services to the children At what point and in what cases do we intend *to say that the break up of the multi generational family* makes for personality development and is good and where does this break up become malign because it prevents the assimilation of good devoted security giving parent figures by the children? Such optimal points between care and independence need to be worked out for each community

*Short term*

We shall have to act in several ways and quickly The 1948 International Congress for Mental Health adopted a statement which described three phases in the development of mental hygiene action [9]

The first consists in segregation and custody of the severest forms of lunacy and idiocy with psychiatric thought confined to the descriptive Linnæan level Many communities have a bare sufficiency of services even in this respect

The second developed after the first world war in some Western countries and concerned itself with therapy—including that of neurosis. Early treatment centres and outpatient work in a broadly psycho-analytic spirit appeared This work gave impetus to research and thought on the ætiological level, which was also fed back into improved provision of therapy and teaching in *mental hospitals Such provision for treatment must be* made—not necessarily in slavish imitation of what has been done in Western countries It will give us research and teaching centres as well as treatment facilities It will be a demonstration of what help can be given and on what theoretical concepts mental health action is based

But the focus of effort should be directed to the third phase—the sending of this trained personnel into the public health services *in the community* In family and child clinics in mothercraft training in industrial welfare and so forth When the usual and well recognised workers in community health—the family doctor the public health staffs and maternity nurses the teachers and the administrators—can adopt the view point and use the skills of the mental hygienist and can see the interaction of society and personality then we shall have begun the work of real prevention

# THE SUTTON COLDFIELD RAILWAY DISASTER

## Evacuation of Casualties

In the derailment of the York-Bristol express at Sutton Coldfield on Jan 23, 17 people were killed and 41 were seriously injured With the considerable resources of the Birmingham area within ten miles, it was possible to treat this number of injured with no more than a spurt from the normal casualty machinery of the local hospitals The first stages of the prearranged plans for dealing with a major catastrophe in the area were in fact put into action, but it turned out that the hospitals were able to cope without taking any of the later steps that had been agreed upon

Last year [1] the Ministry of Health suggested to hospitals and local health authorities some ways in which their organisations for dealing with big accidents might be improved, and the effective handling of the casualties at Sutton Coldfield has again illustrated the importance of detailed preparedness The emergency plan which had been decided upon for the Birmingham hospitals had been drawn up in cooperation with the police, the ambulance authorities, the general practitioners, the industrial medical officers, and the voluntary organisations This was, of course, only a part of the response evoked by this particular accident, the greater share being contributed by the organisation for Sutton Coldfield itself, and particularly by the local general practitioners, but it may be useful to summarise some of its provisions, which no doubt are much the same as those that have been agreed to in other parts of the country

### *The Birmingham Plan*

A major catastrophe is defined as one involving 50 or more seriously injured casualties, *or* one that is determined as such by the duty officer at the fire and ambulance control centre in the light of the circumstances The decision as to whether the plan should come into operation is thus the responsibility of the duty officer at the control centre, though he will consult if necessary with the medical officer in charge of casualty services (who will go to the spot) and the medical coördinating officer (who will go to the control centre)

When a catastrophe is declared, it is the task of the hospital services to provide (*a*) a team or teams of doctors and nurses, with equipment drawn from hospitals, to join in setting up first aid posts at the scene of the accident, and (*b*) a medical officer in charge of the casualty services, who will organise and direct first aid on the spot, and pass back information about the nature and number of the casualties to the medical coördinating officer, who will ensure that the first-aid teams get what they want and that the casualties are taken to the hospitals best prepared to receive them

At the same time the police will send two wireless cars to the scene and establish an "incident post" which will be in touch by telephone or wireless with the control centre and the central police information room The police will also provide a limited quantity of first aid equipment It will be their responsibility to record the names and addresses of those involved, and to give information to inquirers at the scene or via the police information room ("The importance of the police obtaining such information cannot be minimised, but on no account will ambulances be delayed for this purpose") If necessary the police will arrange special mortuary accommodation near the scene

At the outset the duty officer at the control centre will tell the doctors and administrators chiefly concerned what has happened, and he will direct to the scene ambulances, emergency equipment, control van, canteen van, floodlight tender, and fire fighting equipment

At the scene the medical officer in charge of the casualty services, who will be a senior surgeon, will keep in close touch with the senior police officer and the senior fire and ambulance officer His duty will be the organisation and direction of all first aid services, including those offered by people who go to the accident on their own initiative He will advise the medical coördinating officer how many casualties there are likely to be and how things are going

At the control centre, the medical coordinating work in conjunction with representatives of the fire and ambulance service, the St John Ambula the Red Cross, the executive council, and the authorities to see that all the arrangements go best possible way

General practitioners and other doctors the scene within a few moments of the acci Birmingham authorities decided that it would put out hospital first aid teams in support consisting of 1 doctor and 4 nurses, are on imme hospitals in the area, and another 10 teams are two hours' call The plan sets out in detail the which the teams will take with them.

The blood transfusion service will be asked to squad, including specially trained personnel of the Ambulance Brigade and the British Red Cross industrial medical officer, if possible with a first a nearby factory, will also report to the incident

The clerk of the executive council will ask 3 tioners in the neighbourhood to help, and another themselves in readiness

The plan also includes details for mobilising the St John Ambulance Brigade and the British Red C

The hospitals themselves will arrange to sending home patients who are fit to go They coördinating officer at half hourly intervals, or if necessary, of the changes in their resources for outpatients and inpatients

This is the outline of a plan that is straightfo precise—the logical application of the m battle evacuation to a thickly populated area Sutton Coldfield accident it was never nece the whole organisation into top gear, but it that it could readily have handled the grav that might have arisen if the Birmingham had run into the wreckage—as so nearly was made plain at Harrow and Wealdstone years ago that any official plan can always flood of unofficial help from all around, and again forthcoming on this occasion Local pr nurses, and many others were quick to res valuable assistance came from a nearby R.A

### *Experiences at the Accident Hospital*

As for the details of the plan, the most c point is just how much in the way of resusc other treatment should be undertaken before are moved to hospital Last week Mr William clinical director of the Birmingham Accident discussed the outcome of the accident colleagues at the Accident Hospital, and one questions they considered was whether a m type of casualty-clearing station could be set site of a serious accident or whether speed was in fact the most important thing to con Mr Gissane and his staff thought that for a ma in Birmingham within, say, five to eight mil Accident Hospital, speed of evacuation to that should be the overriding consideration Once hospital full resuscitation and treatment be brought to bear If the journey to hospital wa miles there was, they felt, a case for setting up a clearing station at the site, although this ob many practical difficulties It would always be of considerable organising difficulty to set up casualty-clearing station at the site of an accide adequate medical control, with a speed in comparable to that of the rescue and ambulance Mr Gissane pointed out that to justify more on the spot it was necessary to establish the clearing station very quickly—say, within fort of the disaster And it was vital that a exceptional experience should be there to ass cases should wait and which should go on Another point to consider was whether the h which the injured were to go had a full emergenc go into action One of the men injured at dfield was in urgent need of resuscitation when the Accident Hospital at 5 15 P M (one hour rash) and the feeling was that this was a case ransfusion might profitably have been started t. The possibility of having specially trained to start transfusions was mentioned One atients might have travelled better if more had been applied. Mr Gissane said that first be simplified by the use of a new type of which was under investigation at the Accident This was made of fibre glass lined with foam l so moulded to the body outline that when the s placed in it the limbs were effectively splinted l movements reduced

[1] See *Lancet* 1954, i 1225

point brought out at the discussion was the e of local knowledge things were much the surgeon in charge at the scene when he was y familiar with the district and with the e ambulance and fire personnel and others oncerned When it comes to supplying informa control centre the difficulty may be to estimate number of casualties which can never be easy injured are entangled in heavy wreckage. It may s be possible for those on the spot to say where ated casualties have gone to or how many have way Clearly if the injured are being extricated different places and taken off by various routes t always be feasible to give the control centre nbers without risk of delaying the ambulances cident Hospital received 13 of the casualties he same number as came in from other sources e same time Sutton Coldfield Cottage Hospital s very close to the accident took most of the the first place and acted as a casualty-clearing n the way to the big hospitals

*n or Resuscitation?*

eryone will agree that there is much of a case ng the removal of shocked patients so that their can be improved by giving plasma or blood s As we said after the Harrow accident[1] ople will think that in an area where big hospitals n easy reach it is better to get the injured away waiting to do more than cover open wounds, ctures, and give morphine and that the only ication for immediate transfusion or operation h seriously shocked person is trapped with little f being got out for some time It may be a matter when there is a long way to go or when by road is likely to be bad In these circum helicopters would be very useful All things d it seems it would be an exceptional accident— ountry at any rate—in which the injured once d, could not be got to hospital so quickly that delay for resuscitation or operation would be ed But that is not to say that arrangements ediate transfusion or surgery should not be in the plan they may rarely be needed but they save life

## NERAL PRACTICE IN SCOTLAND

ixth annual report of the Scottish Medical Committee[2] states that at the end of last ere were 2543 doctors undertaking to provide medical services in Scotland compared with 2505 and 2424 in 1952 As a result of the notional yments many doctors have taken partners for t time or in established partnerships, have d the number of partners For the first time start of the National Health Service the average number of patients on doctors' lists throughout Scotland has fallen below 2000

### ENTRY INTO PRACTICE

During the year 106 doctors died or resigned, and the committee granted 143 new applications for admission to medical lists Of these applications 43 were from doctors who had been selected to fill practice vacancies (including 13 to fill vacancies in partnerships) 82 from doctors who wished to enter into partnership with established doctors, and 18 from doctors who wished to set up new and independent practices In addition there were granted 64 applications from doctors already on medical lists who wished to extend their practices into neighbouring executive-council areas

The committee refused 26 applications for inclusion in lists of which 15 were from doctors wishing to extend their practices into neighbouring areas Of the 11 appeals to the Secretary of State for Scotland against these refusals 2 were withdrawn before a decision was reached in 8 the decision of the committee was upheld and in 1 the decision of the committee was modified 2 other doctors appealed against the imposition of conditions by the committee in granting their applications for admission. In both instances the decision of the committee was upheld

During the year practice vacancies were dealt with as follows

| | | |
|---|---|---|
| (a) Filled after advertisement | | |
| (i) by a doctor new to the area | 24 | |
| (ii) by a doctor already on the medical list for that area | 2 | |
| | — | 26 |
| (b) Filled without advertisement | | |
| (i) by the replacement of a partner | 13 | |
| (ii) by the appointment of a new doctor | 4 | |
| (iii) amalgamated with existing practice or practices | 29 | |
| | — | 46 |
| (c) Dispersed (patients advised to make a fresh choice of doctor) | | 23 |

Of the practices dealt with by amalgamation 6 had lists of under 500 patients and 11 lists of under 1000 All the dispersed practices were small the largest had 527 patients.

Over 800 applications were received for the 20 advertised vacancies. But some applicants applied for more than one vacancy The average age of successful applicants during the year was 30 the range of ages being from 27 to 56 Of the 13 appeals by unsuccessful applicants, 1 was withdrawn 9 were determined summarily; and 3 were decided after a hearing In 2 instances both after a hearing the decision of the executive council was overturned In the remainder the selection of the executive council was upheld When an appeal is successful the committee directs that the successful appellant be appointed instead of or in addition to the doctor selected by the executive council

### CERTIFICATES IN CONNECTION WITH GOODWILL

The committee considered 26 applications for a certificate that a proposed transaction did not involve unlawful sale or purchase of the goodwill of a practice Where the committee was at first unable to grant the desired certificate most of the applicants submitted amended proposals which justified a certificate The committee draws attention to the fact that the sale of goodwill is prohibited no matter how indirect that sale may be The performance of services for an unreasonably low return for instance is deemed to constitute the sale of goodwill whatever the intention of the parties may be The committee appreciates that difference in age experience and ability of the partners justifies some initial disparity in shares of the profits but as the new partner gains in experience and assumes a greater responsibility in the work of the practice his share in the returns should increase proportionately if the return for his services is to be regarded as reasonable

---

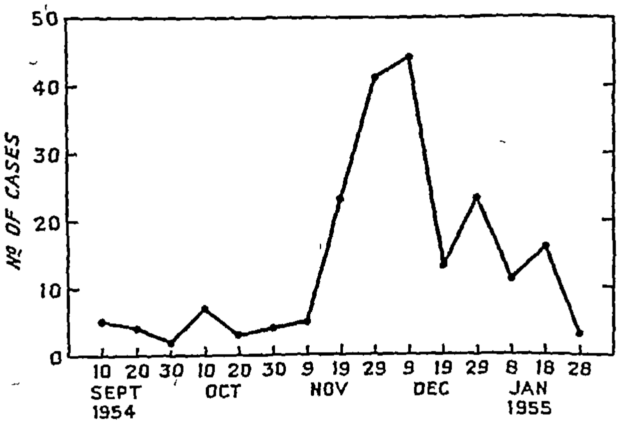
## INFLUENZA

This winter's influenza seems to have been mostly due, until now, to the B virus There were a few cases of influenza-B infection in the spring of 1954, and the virus was found in Wales in September, and then in the North of England, in Scotland, and, more recently, in the South of England The over all incidence in the country has not been so high as during epidemics of influenza A, all ages have been affected, but there has been a high attack-rate in children The last epidemic of influenza B of comparable size in this country was in 1945–46, since when the infection seems to have been endemic with sporadic cases detected each winter Presumably, therefore, the children infected this winter include many who escaped the 1945–46 epidemic

Influenza-A epidemics usually occur every *two to three* years, and in this country we had epidemics in 1947, 1949, 1951, and 1953 This year the influenza A virus has apparently defied the laws of arithmetic, and there have been *only sporadic cases* Elsewhere in the world there have been no reports of major epidemics of influenza An epidemic of influenza B was recently reported from Northern Holland, and cases have been notified from Germany, Malaya, and Canada The winter is not yet over, but in the world as a whole the contrast between this winter's experience so far and that of an epidemic winter is very striking

In England and Wales deaths attributed to influenza in the 160 Great Towns rose from 15 in the week ended Nov 13 to 66 in the week ended Dec 18 In the week ended Dec 25 the total was 56, and in the four weeks ended Jan 1, 8, 15, and 22 the numbers were 82, 102, 134, and 136



**Influenza in a Gloucestershire practice of 3485 patients: new cases plotted at 10-day intervals.**

The prevalence of the disease, which seems to have been greatest in November, has apparently varied between places quite close to each other

### *North of England*

A practitioner in a town near Darlington writes that there the disease was virtually confined to the month between mid-November and mid-December, but there have since been a few sporadic cases In the nearby towns of Darlington and Stockton-on-Tees an epidemic started in the first weeks of November, but in a small village three miles north of his practice there were very few cases, even though many of the adults work in one or other of these towns.

The epidemic, though short-lived, was the worst as regards number and severity, in the past seven years At first the infection affected principally those aged 5–10 years, and at one time the school attendance of those in this age group was only 33–38% of the total

Clinically there was sudden onset of feve sore throat, and sometimes cough, epistax mon, and in several cases this was profu In perhaps a quarter of the cases in ve pyrexia persisted *for five to seven* days, and c took two to three weeks About half the a were severely affected, with gross lassitu febrile phase Among the children the complications Among the adults complicatio pneumonia (4), otitis media (2), and arthriti

TABLE I—AGE DISTRIBUTION OF CASES OF CLIN IN A GLOUCESTERSHIRE PRACTICE, SEPT 1, 19 1955

| Age (yr ) | Male | | | Female | | |
|---|---|---|---|---|---|---|
| | Pop | Influenza | | Pop | Influenza | |
| | | No | % | | No | % |
| 0– 9 | 285 | 22 | 7 7 | 285 | 34 | 11 9 |
| 10–19 | 189 | 23 | 12 2 | 208 | 25 | 12·0 |
| 20–29 | 205 | 5 | 2 4 | 237 | 14 | 5 9 |
| 30–39 | 268 | 6 | 2 2 | 244 | 19 | 7 8 |

| Total | 1738 | 88 | 5 1 | 1747 | 118 | 6 8 |

### *West Country*

A doctor with a mixed urban and rural Devonshire writes

"Here the epidemic started in November b appears to have passed its peak The disease spread and highly infective, has been mild Se cations have been extremely rare Children s been affected more than adults In most case stage has not lasted longer than three or fou occasionally it has lasted for a week or more festations other than pyrexia have been headac sore throat, cough, and gastro intestinal distu colic, vomiting, and diarrhœa For quick rec bed has proved of paramount importance, with the aspirin group for the relief of symptoms. C pyrexia has been prolonged have apparently re aureomycin"

From Gloucestershire a doctor with an rural practice of 3485 patients reports tha Sept 1 and Jan 24 there were 206 cases o influenza" (This he defines as a febrile illness onset, associated with aching and upper r infection) There was a small burst of cases in and a much more severe one in November and with a peak in the ten days between Nov 1 (see accompanying figure) The figures for include an explosive outbreak affecting chil 14 years of age, in whom the syndrome includ severe pyrexia, delirium, and epistaxis One red vision "She saw the world literally re for a few days before the onset of fever" Co have been few, the two commonest were oti

TABLE II—AGE DISTRIBUTION OF THOSE ATTAC INFLUENZA BETWEEN SEPT 1 AND JAN 7 IN 1 295 VOLUNTEERS

| Age (yr ) | Males | Females |
|---|---|---|
| 0– 9 | 23 | 19 |
| 10–19 | 8 | 8 |
| 20–29 | 1 | 7 |

## Medicine and the Law

### A Doctor's Telephone

ndon Executive Council has ruled that a doctor
quired to have a telephone at his residence or
nd that if he has a telephone he is not obliged
patients use the number [1]

ling was given on a complaint by a mother who said
aited all day for the doctor to visit *her 8 year-old*
who had tonsillitis She could not get in touch with
r because as far as she knew he was not on the
She could not go to the surgery because there was
look after the child When her husband arrived home
ning they found another doctor—who treated the
private patient

dical services committee held an inquiry In its
the council it said that the first doctor admitted that
telephone but said it was not available for patients.
mittee considered that there had not been a breach
nditions of service The members of the council
approved of the doctor's conduct, but adopted the
dation that he had not committed a breach of the
service A member of the council suggested that the
ould insist on going on the list of a doctor who was
by telephone

uncil's ruling is clearly correct having regard to
s of service attached to the General Medical and
eutical Services Regulations But these statu
ms of service which must be incorporated in
dividual contract are not exclusive The execu
ncil is entitled to add to them and this can be
en after the contract has been entered into
l the Minister of Health gives his sanction

### Postal Treatment

harmacy and Medicines Act 1941 makes it an
o sell in retail any articles consisting of a substance recommended as a medicine without the appropriate designation or quantitative particulars This does not apply to an article made up and supplied for the use of a particular person being an article prescribed by reference to the needs of that person This exception is essential—without it no chemist could make up a doctor's prescription—but it provides a loophole for firms who claim to treat diseases by post
